

General Description

The MxL7225 is a dual channel, 25A step-down power module. It includes a wide 4.5V to 15V input voltage range and supports two outputs each with an output voltage range of 0.6V to 1.8V, set by a single external resistor. The MxL7225 requires only a few input and output capacitors, which simplifies design and shortens time-to-market. The module supplies either two 25A outputs, a single 50A output or up to 300A when paralleled with additional MxL7225 modules. A unique package design where inductors are mounted externally provides improved thermal performance and lower cost relative to devices with the same industry standard pinout.

The complete switch mode DC/DC power supply integrates the control, drivers, bootstrap diodes, bootstrap capacitors, inductors, MOSFETs and HF bypass capacitors in a single package for point-of-load conversions.

The MxL7225 includes a temperature diode that enables device temperature monitoring. It also has an adjustable switching frequency and utilizes a peak current mode architecture which allows fast line and load transient response.

A host of protection features, including overcurrent, over-temperature, output overvoltage and UVLO, help this module achieve safe operation under abnormal operating conditions.

The MxL7225 is available in a space saving 16mm x 16mm x 5.01mm RoHS compliant BGA package.

The MxL7225-1 is identical to the MxL7225 except that there are no internal feedback loop compensation components. When more flexibility is desired in dealing with loop characteristics, the MxL7225-1 allows the system designer to use an external compensation network entirely different from that embedded in the MxL7225.

Typical Application

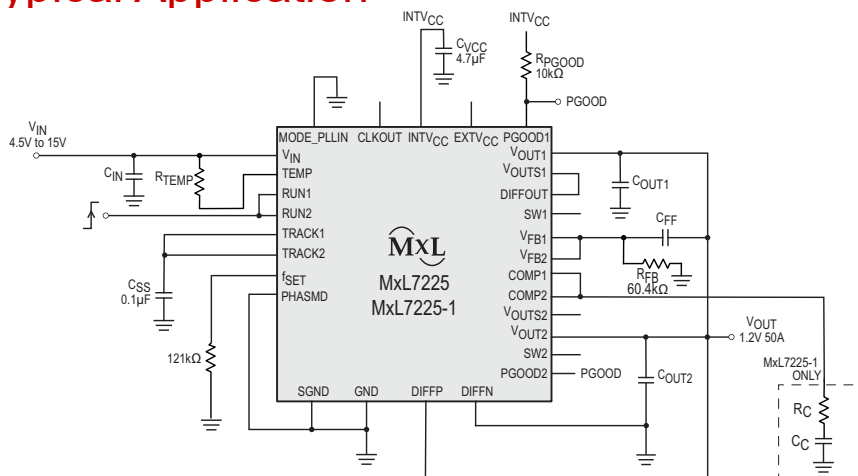

Figure 1: Typical Application: 50A, 1.2V Output DC/DC Power Module

Features

- Dual 25A or single 50A output
- Input voltage range: 4.5V to 15V
- Output voltage range: 0.6V to 1.8V
- Multiphase current sharing with multiple MxL7225s for up to 300A output
- Frequency synchronization
- Differential remote sense amplifier
- Peak current mode architecture for fast transient response
- Adjustable switching frequency (400kHz to 780kHz)
- Overcurrent protection
- Output overvoltage protection
- Internal temperature monitor and thermal shutdown protection
- Thermally enhanced 16mm x 16mm x 5.01mm BGA package

Applications

- Telecom and Networking Equipment
- Industrial Equipment
- Test Equipment

Specifications

Absolute Maximum Ratings

Important: Stress above what is listed in [Table 1](#) may cause permanent damage to the device. This is a stress rating only—functional operation of the device above what is listed in [Table 1](#) or any other conditions beyond what MaxLinear recommends is not implied. Exposure to conditions above what is listed in [Table 3](#) for extended periods of time may affect device reliability. Solder reflow profile is specified in the IPC/JEDEC J-STD-020C standard.

Table 1: Absolute Maximum Ratings

Parameter	Minimum	Maximum	Units
V_{IN}	-0.3	18	V
V_{SW1} , V_{SW2}	-1	25	V
PGOOD1, PGOOD2, COMP1, COMP2	-0.3	6	V
INTV _{CC} , EXTV _{CC}	-0.3	6	V
MODE/PLLIN, f_{SET} , TRACK1, TRACK2	-0.3	INTV _{CC}	V
DIFFOUT	-0.3	INTV _{CC} - 1.1V	V
PHASMD	-0.3	INTV _{CC}	V
V_{OUT1} , V_{OUT2} , V_{OUTS1} , V_{OUTS2}	-0.3	6	V
DIFFP, DIFFN	-0.3	INTV _{CC}	V
RUN1, RUN2, V_{FB1} , V_{FB2}	-0.3	INTV _{CC}	V
INTV _{CC} Peak Output Current		100	mA
Storage Temperature Range	-65	150	°C
Peak Package Body Temperature		245	°C

PGOOD	0	5.5	V
Switching Frequency	400	780	kHz
Junction Temperature Range (T_J)	-40	125	°C
Thermal Resistance from Junction to Ambient (Θ_{JA})		7	°C/W
Thermal Resistance from Junction to PCB (Θ_{JB})		1.5	°C/W
Thermal Resistance from Junction to Top of Module Case (Θ_{Jctop})		3.86	°C/W

Electrical Characteristics

Specifications are for Operating Junction Temperature of $T_J = 25^\circ\text{C}$ only; limits applying over the full Operating Junction Temperature range are denoted by a "•". Typical values represent the most likely parametric norm at $T_J = 25^\circ\text{C}$ and are provided for reference purposes only. Unless otherwise indicated, $V_{IN} = 12\text{V}$ and V_{RUN1} , $V_{RUN2} = 5\text{V}$. Per [Figure 18](#) and [Figure 19](#).

Oscillator and Phase-Locked Loop						
Frequency nominal	Nominal frequency	f _{SET} = 1.2V	450	500	550	kHz
Frequency low	Lowest frequency	f _{SET} = 0.93V		400		kHz
Frequency high	Highest frequency	f _{SET} > 2.4V, up to INTV _{CC}		780		kHz
I _{FSET}	Frequency set current		9	10	11	μA
R _{MODE_PLLIN}	MODE_PLLIN input resistance			250		kΩ
CLKOUT	Phase (relative to SW1)	PHASMD = GND		60		Deg
		PHASMD = float		90		Deg
		PHASMD = INTV _{CC}		120		Deg
CLK high	Clock High output voltage		2			V
CLK low	Clock Low output voltage				0.2	V
Differential Amplifier						
A _V	Gain			1		V/V
R _{IN}	Input resistance	Measured at DIFFP Input		82		kΩ
V _{OS}	Input offset voltage	V _{DIFFP} = V _{DIFFOUT} = 1.5V, I _{DIFFOUT} = 100μA			3	mV
PSRR	Power Supply Rejection Ratio	5V < V _{IN} < 15V		90		dB
I _{CL}	Maximum Output current			3		mA
V _{DIFFOUT(MAX)}	Maximum output voltage	I _{DIFFOUT} = 300μA	INTV _{CC} - 1.4			V
GBW	Gain Bandwidth Product			2.7		MHz
V _{TEMP}	Diode Connected PNP	I = 100μA		0.6		V
TC _{VTEMP}	Temperature Coefficient	I = 25μA	•	-2.1		mV/°C
OT	Thermal shutdown threshold	Rising temperature		145		°C
	Thermal hysteresis			15		°C

1. See output current derating curves for different V_{IN}, V_{OUT} and T_A.
2. The MxL7225 module is designed to operate from 400kHz to 780kHz.

Pin Information

Pin Configuration

Figure 3: Pin Configuration

Pin Description

Table 5: Pin Description

Pin Number	Pin Name	Description
A1, A2, A3, A4, A5, B1, B2, B3, B4, B5, C1, C2, C3, C4	V _{OUT1}	Output of the channel 1 power stage. Connect the corresponding output load from the V _{OUT1} pins to the PGND pins. Direct output decoupling capacitance from V _{OUT1} to PGND is recommended.
A6, A7, B6, B7, D1, D2, D3, D4, D9, D10, D11, D12, E1, E2, E3, E4, E10, E11, E12, F1, F2, F3, F10, F11, F12, G1, G3, G10, G12, H1, H2, H3, H4, H5, H6, H7, H9, H10, H11, H12, J1, J5, J8, J12, K1, K5, K6, K7, K8, K12, L1, L12, M1, M12	GND	Ground for the power stage. Connect to the application's power ground plane.
A8, A9, A10, A11, A12, B8, B9, B10, B11, B12, C9, C10, C11, C12	V _{OUT2}	Output of the channel 2 power stage. Connect the corresponding output load from the V _{OUT2} pins to the PGND pins. Direct output decoupling capacitance from V _{OUT2} to PGND is recommended.

Table 5: Pin Description (Continued)

Pin Number	Pin Name	Description
C5, C8	V _{OUTS1} , V _{OUTS2}	These pins are connected internally to the top of the feedback resistor for each output. Connect this pin directly to its specific output or to DIFFOUT when using the remote sense amplifier. When paralleling modules, connect one of the V _{OUTS} pins to DIFFOUT when remote sensing or directly to V _{OUT} when not remote sensing. These pins must be connected to either DIFFOUT or V _{OUT} . This connection provides the feedback path and cannot be left open.
C6	f _{SET}	This pin is used to set the operating frequency via one of two methods: <ul style="list-style-type: none"> ■ Connect a resistor from this pin to ground ■ Drive this pin with a DC voltage This pin sources a 10μA current. See Figure 24 for frequency of operation vs. f _{SET} voltage.
C7, D6, G6, G7, F6, F7	SGND	Ground pin for all analog signals and low power circuits. Connect to GND in one place. See layout guidelines in Figure 36 .
D5, D7	V _{FB1} , V _{FB2}	Feedback input to the negative side of the error amplifier for each channel. These pins are each internally connected to V _{OUTS1} and V _{OUTS2} via a precision 60.4kΩ resistor. Vary each output voltage by adding a feedback resistor from V _{FB} to SGND. Tie V _{FB1} and V _{FB2} together for parallel operation.
E5, D8	TRACK1, TRACK2	Soft-Start and Output Voltage Tracking pins. Each channel has a 1.25μA pull-up current source. When one channel is configured as a master, adding a capacitor from this pin to ground sets a soft-start ramp rate. The other channel can be set up as the slave and have the master output applied through a voltage divider to the slave's output TRACK pin. For coincidental tracking, this voltage divider is equal to the slave's output feedback divider.
E6, E7	COMP1, COMP2	Current control threshold and error amplifier compensation point for each channel. The current comparator threshold increases with this control voltage. The MxL7225 is internally compensated, however a feed-forward C _{FF} is frequently required. R _C and C _C are required for MxL7225-1 (not MxL7225). Refer to Figure 18 , Table 7 and Stability and Compensation in the Applications Information section. When paralleling both channels, connect the COMP1 and COMP2 pins together.
E8	DIFFP	This pin is the remote sense amplifier's positive input and is connected to the output voltage's remote sense point. If the remote sense amplifier is not used, connect this pin to SGND.
E9	DIFFN	This pin is the remote sense amplifier's negative input and is connected to the remote sense point GND. If the remote sense amplifier is not used, connect this pin to SGND.
F4	MODE_PLLIN	Selects between Forced Continuous Mode or Pulse-Skipping Mode, or connects to an external clock for frequency synchronization. There are three connection options: <ol style="list-style-type: none"> 1. Connect this pin to SGND to force both channels into Forced Continuous Mode. 2. Connect this pin to INTV_{CC} or leave it floating to enable Pulse-Skipping Mode. 3. Connect this pin to an external clock. Both channels will be synchronized to the clock and operate in Forced Continuous Mode.
F5, F9	RUN1, RUN2	The RUN1 and RUN2 pins each enable and disable their corresponding channel. A voltage above 1.27V on the RUN pin will turn on the corresponding channel. The RUN pin has a hysteresis of about 170mV. There are two supported methods to drive the RUN pin. Either drive it with a logic signal or connect it to a voltage divider whose upper resistor is connected to V _{IN} and lower resistor to ground. See Applications Information for important details.
F8	DIFFOUT	Output of the internal remote sense amplifier. If remote sensing on channel 1, connect to V _{OUTS1} . If remote sensing on channel 2, connect to V _{OUTS2} . When paralleling modules, connect one of the V _{OUTS} pins to DIFFOUT when remote sensing.
G2, G11	SW1, SW2	Use these pins to access the switching node of each channel. An RC snubber can be connected to reduce switch node ringing. Otherwise, leave these pins floating.

Table 5: Pin Description (Continued)

Pin Number	Pin Name	Description
G4	PHASMD	This pin selects the CLKOUT phase as follows: <ul style="list-style-type: none"> ■ Connect to SGND for 60 degrees ■ Connect to INTV_{CC} for 120 degrees ■ Leave floating for 90 degrees
G5	CLKOUT	This is the clock output. Its phase is set with the PHASMD pin. It is used to synchronize multiple modules so that all channels evenly share load current and operate in a multiphase manner. Refer to the Application Section on Multiphase Operation for more details.
G9, G8	PGOOD1, PGOOD2	Power Good outputs. This open-drain output is pulled low when the V _{OUT} of its respective channel is more than ±10% outside regulation.
H8	INTV _{CC}	Internal 5V Regulator Output. This voltage powers the control circuits and internal gate driver. Decouple to GND with a 4.7µF ceramic capacitor. INTV _{CC} is activated when either RUN1 or RUN2 is activated.
J6	TEMP	The internal temperature sensing diode monitors the temperature change with voltage change on V _{BE} . Connect to V _{IN} through a resistor (R _{TEMP}) to limit the current to 100µA. $R_{TEMP} = (V_{IN} - 0.6V) / 100\mu A$
J7	EXTV _{CC}	External power input that is connected through an internal switch to INTV _{CC} whenever EXTV _{CC} is > 4.7V. Do not exceed 6V on this input. Connect this pin to V _{IN} when operating V _{IN} on 5V. An efficiency increase that is a function of (V _{IN} - INTV _{CC}) multiplied by the power MOSFET driver current occurs when the feature is used. V _{IN} must be applied before EXTV _{CC} , and EXTV _{CC} must be removed before V _{IN} .

Functional Block Diagrams

Figure 16: MxL7225 Functional Block Diagram

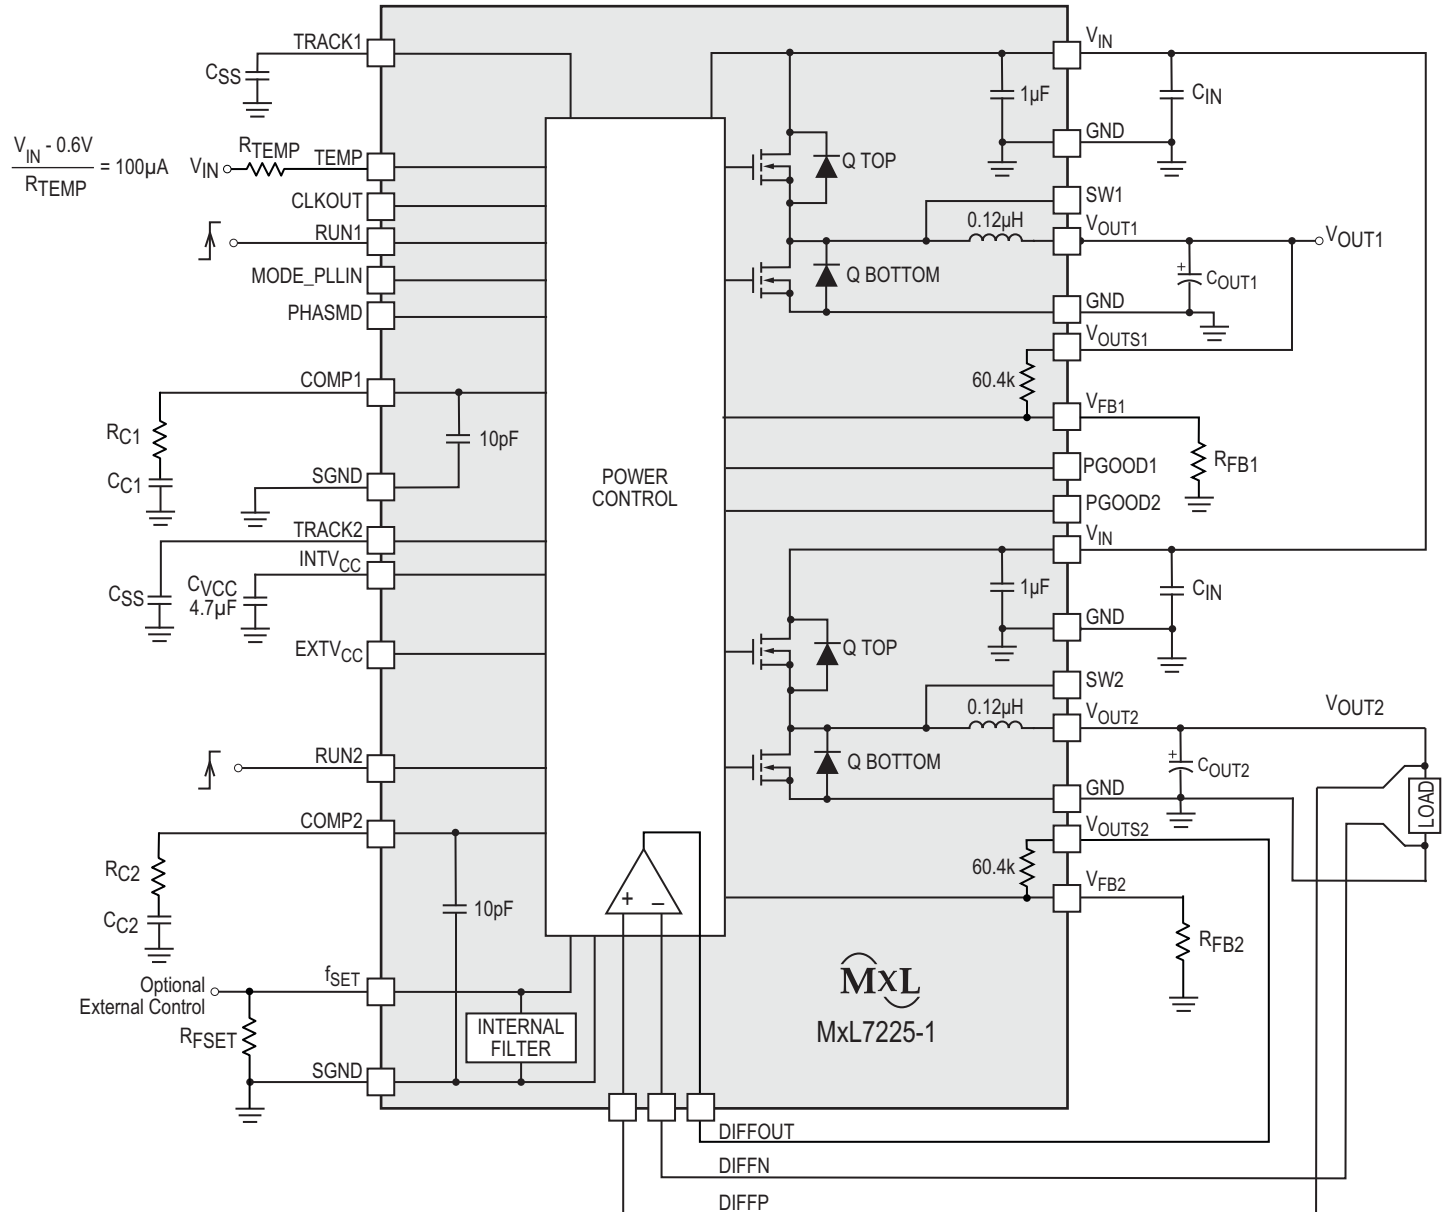

Figure 17: MxL7225-1 Functional Block Diagram

Operation

Power Module Description

The MxL7225 is a dual-channel, standalone, synchronous step-down power module that provides two 25A outputs or one 50A output. This power module has a continuous input voltage range of 4.5V to 15V and has been optimized for 12V conversions. It provides precisely regulated output voltages from 0.6V to 1.8V that are set by a single external resistor. See the typical application schematic in [Figure 18](#).

The module employs a constant frequency, peak current mode control loop architecture. It also has an internal feedback loop compensation. These features ensure the MxL7225 has sufficient stability margins as well as good transient performance over a wide range of output capacitors, including low ESR ceramic capacitors.

The peak current mode control supports cycle-by-cycle fast current limit and current limit hiccup in overcurrent or output short circuit conditions. The open-drain PGOOD outputs are pulled low when the output voltage exceeds $\pm 10\%$ of its set point. Once the output voltage exceeds $+10\%$, the high side MOSFET is kept off while the low side MOSFET turns on, clamping the output voltage. The overvoltage and undervoltage detection are referenced to the feedback pin.

The RUN1 and RUN2 pins enable and disable the module's two channels. Pulling a RUN pin below 1.1V forces the respective regulator into shutdown mode and turns off both the high side and low side MOSFETs. The TRACK pins are used for either programming the output voltage ramp and voltage tracking during start-up, or for soft-starting the channels.

The MxL7225 includes a differential remote sense amplifier (with a gain of +1). This amplifier can be used to accurately sense the voltage at the load point on one of the module's two outputs or on a single parallel output.

The switching frequency is programmed from 400kHz to 780kHz using an external resistor on the f_{SET} pin. For noise sensitive applications, the module can be synchronized to an external clock.

The MxL7225 module can be configured to current share between channels or can also be set to current share between modules (multiphase or ganged operation). Using the MODE_PLLIN, PHASMD and CLKOUT pins, multiphase operation of up to 12 phases is possible with multiple MxL7225s running in parallel.

Using the MODE_PLLIN pin to operate in pulse-skipping mode results in high efficiency performance at light loads. This light load feature extends battery life.

The EXTV_{CC} pin allows an external 5V supply to power the module and eliminate power dissipation in the internal 5V LDO. EXTV_{CC} has a threshold of 4.7V for activation and a max operating rating of 5.5V. It must sequence on after V_{IN} and sequence off before V_{IN} .

Monitor the internal die temperature by using the TEMP pin. Pull the anode up to V_{IN} through an external resistor to set the bias current in the diode. Thermal simulation has shown that the thermal monitor on the controller die is within 5°C of the MOSFETs.

The MxL7225-1 is identical to the MxL7225 except that there are no internal control loop compensation components. When dealing with an atypical selection of output capacitors or when further loop optimization is desired, the MxL7225-1 offers more flexibility.

Applications Information

Typical Application Circuit

The typical MxL7225 application circuit is shown in [Figure 18](#). External component selection is primarily determined by the maximum load current and output voltage. Refer to [Table 7](#) for a selection of various design solutions. Additional information about selecting external compensation components can be found in the [Stability and Compensation](#) section.

V_{IN} to V_{OUT} Step-Down Ratios

For a given input voltage, there are limitations to the maximum possible V_{IN} and V_{OUT} step-down ratios.

The MxL7225 has a maximum duty cycle of 90% at 500kHz, meaning that the maximum output voltage will be approximately $0.9 \times V_{IN}$. When running at a high duty cycle, output current can be limited by the power dissipation in the high-side MOSFET. The minimum output voltage from a given input is controlled by the minimum on-time, which is 90ns. The minimum output voltage is either $V_{IN} \times f_{SW}(\text{MHz}) \times 0.09\mu\text{s}$ or 0.6V, whichever is higher. To get a lower output voltage, reduce the switching frequency.

Figure 18: Typical $4.5V_{IN}$ to $15V_{IN}$, 1.5V and 1.2V at 25A Outputs, MxL7225

Figure 19: Typical $4.5V_{IN}$ to $15V_{IN}$, 1.5V and 1.2V at 25A Outputs, MxL7225-1

Output Voltage Programming

The PWM controller has an internal 0.6V reference. A resistor R_{FB} between the V_{FB} and SGND pins programs the output voltage. A 60.4k Ω internal feedback resistor is connected from V_{OUTS1} to V_{FB1} and from V_{OUTS2} to V_{FB2} , as illustrated in the functional block diagram.

R_{FB} values for corresponding standard V_{OUT} values are shown in [Table 6](#). Use the following equation to determine the R_{FB} value for other V_{OUT} levels:

$$R_{FB} = \frac{0.6V \times 60.4k\Omega}{V_{OUT} - 0.6V} \quad \text{Equation 1}$$

In the case of paralleling multiple channels and devices, when all V_{FB} pins are tied together and only one V_{OUTS} pin is connected to the output, a common R_{FB} resistor may be used. Select the R_{FB} as explained above. Note that each V_{FB} pin has an I_{FB} max of 20nA. To reduce V_{OUT} error due to I_{FB} , use an additional R_{FB} and connect the corresponding V_{OUTS} to V_{OUT} as shown in [Figure 21](#).

Table 6: V_{FB} Resistor Table vs. Various Output Voltages

V_{OUT}	0.6V	0.8V	1.0V	1.2V	1.5V	1.8V
R_{FB}	Open	182k	90.9k	60.4k	40.2k	30.2k

Input Capacitors

Use four 22 μ F ceramic input capacitors to reduce RMS ripple current on the regulator input.

A bulk input capacitor is required if the source impedance is high or the source capacitance is low. For additional bulk input capacitance, use a surface mount 47 μ F to 100 μ F aluminum electrolytic bulk capacitor.

Output Capacitors

The output capacitors, denoted as C_{OUT} , need to have low enough equivalent series resistance (ESR) to meet output voltage ripple and transient requirements. The MxL7225 can use low ESR tantalum capacitors, low ESR polymer capacitors, ceramic capacitors or a combination of those for C_{OUT} . Refer to [Table 7](#) for C_{OUT} recommendations that optimize performance for different output voltages.

Pulse-Skipping Mode Operation

The pulse-skipping mode enables the module to skip cycles at light loads which reduces switching losses and increases efficiency at low to intermediate currents. To enable this mode, connect the MODE_PLLIN pin to the INTV_{CC} pin.

Forced Continuous Operation

Forced continuous operation is recommended when fixed frequency is more important than light load efficiency, and when the lowest output ripple is desired. To enable this mode, connect the MODE_PLLIN pin to GND.

Multiphase Operation

Multiphase operation is used to achieve output currents greater than 25A. It can be used with both MxL7225 channels to achieve one 50A output. It can also be used by paralleling multiple MxL7225s and running them out of phase to attain one single high current output, up to 300A. Ripple current in both the input and output capacitors is substantially lower using a multiphase design, especially when the number of phases multiplied by the output voltage is less than the input voltage. Input RMS ripple current and output ripple amplitude is reduced by the number of phases used while the effective ripple frequency is multiplied by the number of phases used. The MxL7225 is a peak current mode controlled device which results in very good current sharing between parallel modules and balances the thermal loading. [Figure 20](#) shows an example of a 2-module, 4-phase, single output regulator that can handle load current up to 100A.

Up to 12 phases can be paralleled by using each MxL7225 channel's PHASMD, MODE_PLLIN and CLKOUT pins. When the CLKOUT pin is connected to the following stage's MODE_PLLIN pin, the frequency and the phase of both devices are locked. Phase difference can be obtained between MODE_PLLIN and CLKOUT of 120 degrees, 60 degrees or 90 degrees respectively by connecting the PHASMD pin to INTV_{CC}, SGND or by floating it. [Figure 21](#) shows an example of parallel operation and [Figure 22](#) shows examples of 2-phase, 4-phase and 6-phase designs.

Figure 20: MxL7225 2-Module, 4-Phase, 1.2V, 100A Regulator

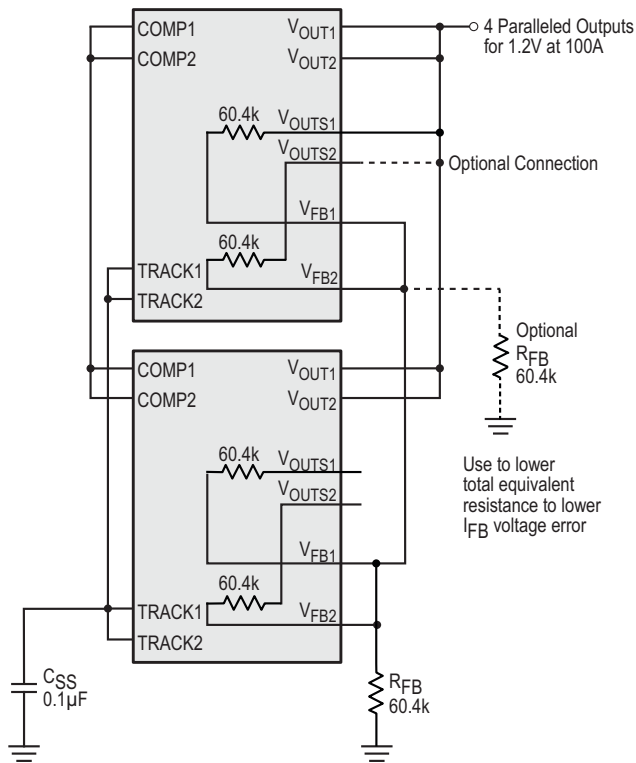

Figure 21: 4-Phase Parallel Configuration

When paralleling multiple channels and devices:

- Tie all V_{FB} pins together.
- Tie all RUN pins together.
- Connect only one of the V_{OUTS} pins to V_{OUT} (or DIFFOUT in the case of remote sensing). In this case, only the R_{FB} corresponding to that V_{OUTS} pin should be populated. Refer to **Output Voltage Programming** for the calculation of R_{FB}. All other V_{OUTS} pins should be left floating.
- If V_{OUT} offset created by I_{FB} (20nA max per channel) is a concern, additional R_{FB} resistors may be populated to mitigate the effect. In such a configuration, each R_{FB} should be the same resistance value as that in the single R_{FB} case, and the corresponding V_{OUTS} pin should be connected to V_{OUT} (or DIFFOUT in the case of remote sensing).
- If remote sensing, only one differential amplifier should be used.
- In MxL7225-1, external R_C and C_C components are required. Only one R_C and one C_C are needed given that all COMP pins are tied together.

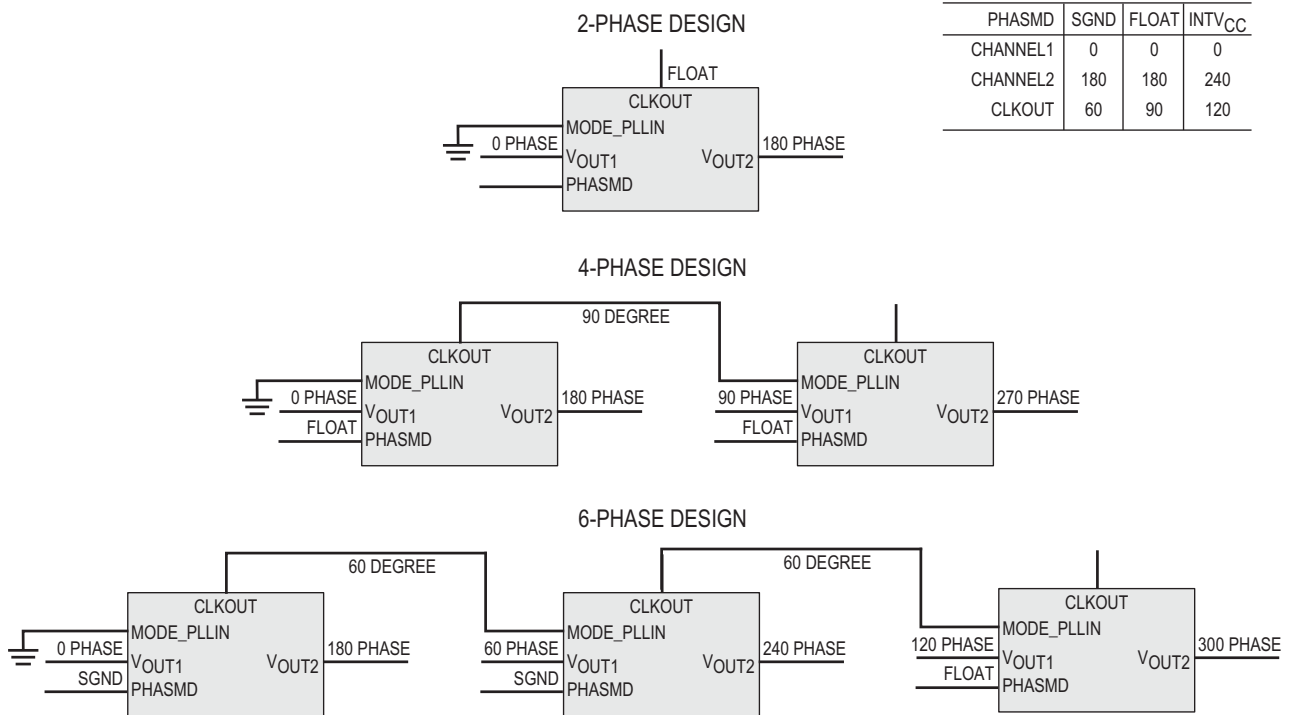

Figure 22: Examples of 2-Phase, 4-Phase and 6-Phase Operation with PHASMD Table

Input Ripple Current Cancellation

Figure 23 illustrates the RMS ripple current reduction that is expected as a function of the number of interleaved phases.

Figure 23: Input RMS Current to DC Load Current Ratio as a Function of Duty Cycle

Frequency Selection and Phase-Locked Loop

To increase efficiency, the MxL7225 works over a range of frequencies. For lower output voltages or duty cycles, lower frequencies are recommended to lower MOSFET switching losses and improve efficiency. For higher output voltages or duty cycles, higher frequencies are recommended to limit inductor ripple current. Refer to the efficiency graphs and their operating frequency conditions. When selecting an operating frequency, keep the highest output voltage in mind.

Use an external resistor between the f_{SET} pin and SGND to set the switching frequency. An accurate $10\mu A$ current source into the resistor sets a voltage that programs the frequency. Alternatively, a DC voltage can be applied to

f_{SET} to program the frequency. Figure 24 illustrates the operating frequency versus the f_{SET} pin voltage.

An external clock with a frequency range of 400kHz to 780kHz and a voltage range of 0V to $INTV_{CC}$ can be connected to the MODE_PLLIN pin. The high level threshold of the clock input is 1.6V and the low level threshold of the clock input is 1V.

The MxL7225 integrates the PLL loop filter components. Ensure that the initial switching frequency is set with an external resistor before locking to an external clock. Both regulators will operate in continuous mode while being synchronized to an external clock signal.

The PLL phase detector output charges and discharges the internal filter network with a pair of complementary current sources. When an external clock is connected, an internal switch disconnects the external f_{SET} resistor. The switching frequency then locks to the incoming external clock. If no external clock is connected, then the internal switch is on, which connects the external f_{SET} resistor.

Figure 24: Operating Frequency vs. f_{SET} Pin Voltage

Minimum On-Time

Minimum On-Time $t_{ON(MIN)}$ is the shortest time that the controller can turn on the high-side MOSFET of either channel. Approaching this time may be more of an issue in low duty cycle applications. Use the following equation to make sure the on-time is above this minimum:

$$\frac{V_{OUT}}{V_{IN} \times \text{FREQ}} > t_{ON(MIN)} \quad \text{Equation 2}$$

If the on-time falls below this minimum, the channel will start to skip cycles. In this case, the output voltage continues to regulate, however output ripple increases. Lowering the switching frequency increases on-time. The minimum on-time specified in the electrical characteristics is 90ns.

Soft-Start and Output Voltage Tracking

A capacitor C_{SS} can be connected from the TRACK pin to ground to implement soft-start. The TRACK pin is charged by a $1.25\mu\text{A}$ current source up to the reference voltage and then on to INTV_{CC} . The MxL7225 has a smooth transition from TRACK to V_{OUT} as shown in Figure 25. If the RUN pin is below 1.2V, the TRACK pin is pulled low. The following equation can be used to calculate soft-start time, defined as when PGOOD asserts:

$$t_{\text{SOFTSTART}} = \frac{C_{SS}}{1.25\mu\text{A}} \times 0.65\text{V} \quad \text{Equation 3}$$

Figure 25: V_{OUT} and V_{TRACK} versus Time

The MODE_PLLIN pin selects between forced continuous mode or pulse-skipping mode during steady-state operation. Regardless of the mode selected, the module channels will always start in the pulse-skipping mode up to $\text{TRACK} = 0.54\text{V}$, beyond which point the operation mode will follow the MODE_PLLIN setting.

The TRACK pins can be used to externally program the output voltage tracking. The output may be tracked up and down with another regulator. The master regulator's output is divided down with an external resistor divider that is the same as the slave regulator's feedback divider to implement coincident tracking. Note that each MxL7225 channel has an internal accurate $60.4\text{k}\Omega$ for the top feedback resistor. Refer to the equation below, which is applicable for $V_{\text{TRACK(SLAVE)}} < 0.8\text{V}$. An example of coincident tracking is shown in Figure 26.

$$V_{\text{OUT(SLAVE)}} = \left(1 + \frac{60.4\text{k}}{R_{\text{TA}}}\right) \times V_{\text{TRACK(SLAVE)}} \quad \text{Equation 4}$$

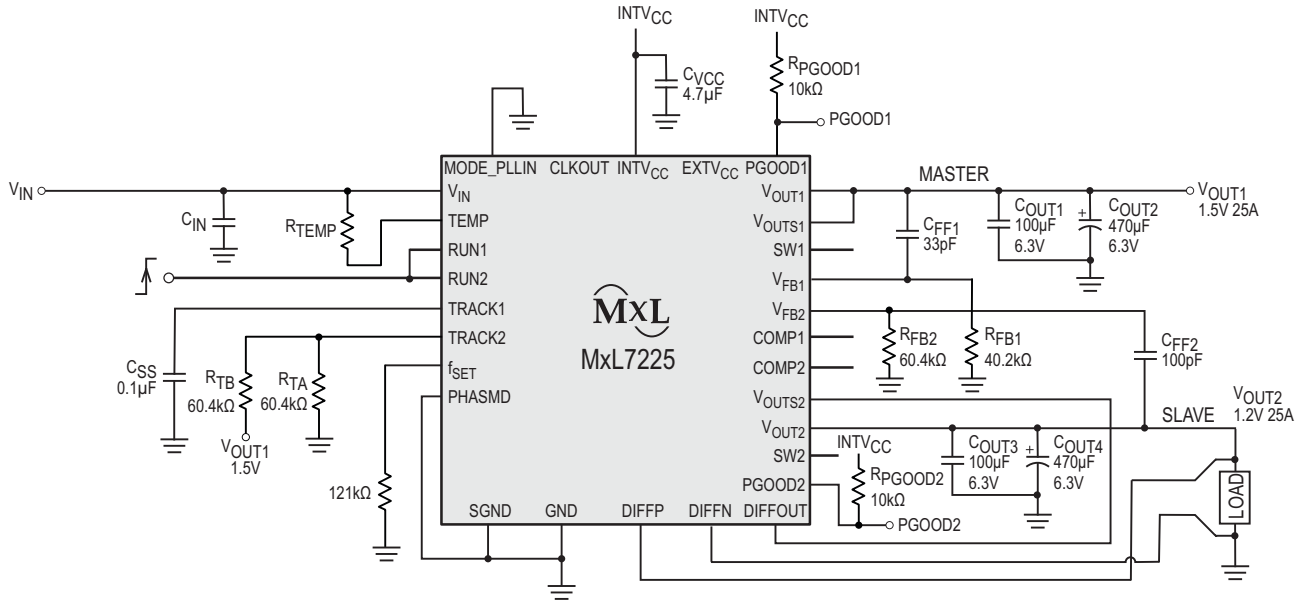

Figure 26: Example of Output Tracking Application Circuit

Figure 27: Output Coincident Tracking Waveform

The ramping voltage is applied to the track pin of the slave. Since the same resistor values are used to divide down the output of the master and to set the output of the slave, the slave tracks with the master coincidentally until its final value is achieved. The master continues from the slave's regulation point to its final value. In [Figure 26](#), R_{TA} is equal to R_{FB2} for coincident tracking.

Power Good

Each channel's open drain PGOOD pin can be used to monitor if its respective V_{OUT} is outside $\pm 10\%$ of the set point. The PGOOD pin is pulled low when the output of the corresponding channel is outside the monitoring window, the RUN pin is below its threshold (1.25V), or the MxL7225 is in the soft-start or tracking phase. The PGOOD pin will go high impedance immediately after V_{FB} voltage is within the monitoring window. Note that there is an internal $20\mu s$ glitch filtering in PGOOD when V_{FB} voltage goes out of the monitoring window.

If desired, a pullup resistor can be connected from the PGOOD pins to a supply voltage with a maximum level of 6V.

Stability and Compensation

The MxL7225 module is internally compensated for stability over a wide range of operating conditions. Refer to [Table 7](#) for recommended configurations. For other configurations or for MxL7225-1 loop compensation, please consult a Maxlinear Field Applications Engineer.

Enabling Channels

There are two supported methods to enable and disable each channel.

Method 1

Method 1 is to drive the RUNx pin of the channel to be enabled (CHx) with a logic signal as shown in [Figure 28](#).

Figure 28: RUNx Pin Driven by a Logic Signal

V_{IN} should be in the operating range (4.5V to 15V) before the logic signal at RUNx goes high. The logic high level must be above 1.3V in order to ensure that the RUNx threshold is crossed. To disable a channel (CHx), the logic signal at the corresponding RUNx pin must be brought down to 1.1V or below.

Method 2

Method 2 is a self-start method. This method uses a resistor divider to divide down V_{IN} and drive the RUNx pin with the divided voltage. The choice of the resistor divider ratio depends on the V_{IN} range.

[Figure 29](#) shows the self-start method for an application where V_{IN} is in the range of 5.5V to 15V.

Figure 29: Self-Start for V_{IN} Range of 5.5V to 15V

Resistors R_1 and R_2 divide V_{IN} down and the divided voltage drives the RUNx pin. The R_1 and R_2 values are chosen such that V_{IN} reaches 5V before RUNx crosses the

RUN threshold. Equation 5 shows the relationship between R_1 , R_2 and $V_{IN(TH)}$ which is the V_{IN} value when the RUNx voltage crosses 1.26V:

$$1 + \frac{R_1}{R_2} = \frac{V_{IN(TH)}}{1.26V} \quad \text{Equation 5}$$

Select R_1 and R_2 by letting $V_{IN(TH)} = 5V$.

If the application is for $V_{IN} = 12V$, the choice of $V_{IN(TH)}$ for Equation 5 can be higher than 5V but less than the minimum of the V_{IN} tolerance band. For example, if V_{IN} is $12V \pm 10\%$, then choose a $V_{IN(TH)}$ between 5V and 10V. A zener diode from RUNx pin to ground is optional for protection of the RUNx pin (to clamp RUNx to 5V) in the event of the R_2 resistor not being connected due to a board level fault.

[Figure 30](#) shows the self-start method for an application where V_{IN} is in the range of 4.5V to 5.5V.

Figure 30: Self-Start for V_{IN} Range of 4.5V to 5.5V

In an application where V_{IN} is the range of 4.5V to 5.5V, it is required to connect V_{IN} to $EXTV_{CC}$. Select R_1 and R_2 based on Equation 5, but use 4V for $V_{IN(TH)}$.

A combination of Method 1 and Method 2 is also recommended where an open drain output drives the RUNx pin with the voltage divider (R_1 and R_2) in place. Criteria for the selection of R_1 and R_2 must be followed as described above.

It is important to note that starting up the channels with RUNx floating is not allowed.

INTV_{CC} and EXTV_{CC}

The V_{IN} input voltage powers an internal 5V low dropout linear regulator. The regulator output (INTV_{CC}) provides voltage to the control circuitry of the module. Alternatively, the EXTV_{CC} pin allows an external 5V supply to be used to eliminate the 5V LDO power dissipation in power sensitive applications.

Differential Remote Sense Amplifier

The MxL7225's differential remote sense amplifier can be used to accurately sense voltages at the load. This is particularly useful in high current load conditions. The DIFFP and DIFFN pins must be connected properly to the remote load point, and the DIFFOUT pin must be connected to the corresponding V_{OUTS1} or V_{OUTS2} pin. The differential amplifier is able to handle an input up to 3.3V.

If a C_{FF} feed-forward capacitor is desirable in a channel employing the differential amplifier, connect the capacitor between V_{FB} and DIFFP instead of DIFFOUT.

SW Pins

Use the SW pins to monitor the switching node of each channel. These pins are generally used for testing or monitoring. During normal operation, these pins should be unconnected and left floating. However, in conjunction with an external series R-C snubber circuit, these pins can be used to dampen ringing on the switch node caused by LC parasitics in the switched current paths.

Temperature Monitoring (TEMP)

An internal temperature sensing diode / PNP transistor is used to monitor its V_{BE} voltage over temperature, thus serving as a temperature monitor. Its forward voltage and temperature coefficient are shown in the electrical characteristics section and plotted in Figure 31. It is connected to V_{IN} through a pullup resistor R_{TEMP} to limit the current to 100μA. It is recommended to set a 60μA minimum current in applications where V_{IN} varies over a wide range. See Figure 32 for an example on how to use this feature.

Figure 31: Diode Voltage vs. Temperature

For accurate temperature measurement, the temperature sensing diode should first be characterized in a controlled temperature environment such as an oven. Without powering up the module, push a constant current such as 100μA into the TEMP pin and out the GND. Measure the diode voltage at two extreme temperature points. TEMP voltage vs diode temperature for said current is simply a straight line between those two points.

Figure 32: 2-Phase, 1V at 50A with Temperature Monitoring

Fault Protection

The MxL7225 module has built-in overcurrent, output overvoltage, and over-temperature protection.

The overcurrent triggers at a nominal load of 35A. Overcurrent during four consecutive switching cycles initiates a hiccup mode. During hiccup, the high-side and low-side MOSFETs are turned off for 100ms. A soft-start is attempted following the hiccup. If the overcurrent persists, the hiccup will continue.

The overvoltage triggers when the output voltage is 10% above the set-point. In overvoltage mode, the gate-source voltage of the top FET is kept at 0V and the bottom FET is kept on.

The over-temperature triggers at 145°C. In an over-temperature state, both top and bottom FETs are kept off. When the temperature cools down below 130°C, the module soft-starts.

Since an output overvoltage event is likely caused by a top FET that has failed short, in the case of an input supply that is capable of delivering high power, it is recommended that a fuse be used at the input. This is so that the bottom FET when kept on would cause high input current to flow through the fuse and quickly disengage the input supply and therefore de-energize the faulty module, preventing further damage to the end product.

Thermal Considerations and Output Current Derating

The design of the MxL7225 module removes heat from the bottom side of the package effectively. Thermal resistance from the bottom substrate material to the printed circuit board is very low.

Proper thermal design is critical in controlling device temperatures and in achieving robust designs. There are many factors that affect the thermal performance. One key factor is the temperature rise of the devices in the package, which is a function of the thermal resistances of the devices inside the package and the power being dissipated. The thermal resistances of the MxL7225 are shown in the **Operating Conditions** section of this datasheet. The JEDEC Θ_{JA} thermal resistance provided is based on tests that comply with the JESD51-2A “Integrated Circuit Thermal Test Method Environmental Conditions – Natural Convection” standard. JESD51 is a group of standards whose intent is to provide comparative data based on a standard test condition which includes a defined board construction. Since the actual board design in the final application will be different from the board defined in the standard, the thermal resistances in the final design may be different from those shown.

Figure 33: Thermal Image 12V to 1V, 50A with No Air Flow⁽¹⁾

1. Based on a 6-layer 3.9" x 5.1" Printed Circuit Board with 2oz copper on the outer layers and 1 oz copper on all internal layers).

Power Derating

The current derating curves in [Figure 39](#) through [Figure 42](#) were acquired with the test setup in [Figure 34](#). The EVK (see details in [Figure 33](#)) was placed in a 0.5 cubic feet enclosed space with no forced air flow. The EVK was configured as a dual-phase single-output converter. The EVK was first loaded to 50A at room temperature. Ambient temperature was then gradually elevated until the module's temperature sensing diode reached 125°C. This is where

Load Current starts to decrease from 50A in the curves. Beyond this point as ambient temperature increased, Load Current was decreased to maintain the 125°C diode temperature. These curves are accurate for the test setup in [Figure 34](#) and natural convection.

[Figure 37](#) and [Figure 38](#) are the corresponding power dissipation in the module at room temperature.

Layout Guidelines and Example

The MxL7225's high level of integration simplifies PCB board design. However, some layout considerations are still recommended for optimal electrical and thermal performance.

- Use large PCB copper areas for high current paths, including V_{IN} , V_{OUT1} and V_{OUT2} and GND to minimize conduction loss and thermal stress in the PCB.
- Use a dedicated power ground layer, placed under the module.
- Use multiple vias to interconnect the top layer and other power layers to minimize via conduction loss and module thermal stress.
- Cap or plate over any vias that are directly placed on the pad.
- Use a separated SGND ground copper area for components that are connected to the signal pins. The SGND to GND should be connected underneath the module.
- Place high frequency ceramic input and output capacitors next to the V_{IN} , V_{OUT} and PGND pins to minimize high frequency noise.
- When paralleling modules, connect the V_{FB} , V_{OUT} , and COMP pins together closely with an internal layer. For soft-start mode, the TRACK pins may be tied together via a common capacitor.
- Test points can be brought out for monitoring the signal pins. Only bring out signals for testing purposes when absolutely necessary. Keep test points as close as possible to the module, if possible, to minimize chances of noise coupling.
- COMP1 and COMP2 are sensitive nodes. Make every effort to avoid overlapping a COMP trace with a signal that has fast edges, such as the CLKOUT, the synchronization clock, and the SW. If overlapping is unavoidable, place the COMP trace and the fast edge signal on layers that are separated by a ground plane.

An example layout for the top PCB layer for the BGA package is recommended in [Figure 36](#).
