## **TYPICAL APPLICATION**

## **<sup>1</sup>FEATURES DESCRIPTION**

**<sup>2</sup>** The LMH6555 is an ultra high speed differential line **• Typical Values unless Otherwise Specified.** driver with 53 dB SFDR at 750 MHz. The LMH6555 **• <sup>−</sup><sup>3</sup> dB Bandwidth (VOUT <sup>=</sup> 0.80 <sup>V</sup>PP) 1.2 GHz** features <sup>a</sup> fixed gain of 13.7 dB. An input to the **• ±0.5 dB Gain Flatness (VOUT = 0.80 VPP) 330** device allows the output common mode voltage to be **MHz SET 10** Set independent of the input common mode voltage in order to simplify the interface to high speed **• Slew Rate 1300 V/μs** differential input ADCs. A unique architecture allows **• 2 nd/3rd Harmonics (750 MHz) <sup>−</sup>53/−<sup>54</sup> dBc** the device to operate as <sup>a</sup> fully differential driver or as **• Fixed Gain 13.7 dB a** single-ended to differential converter.

**• Supply Current 120 mA** The outstanding linearity and drive capability (100Ω **•• Single Supply Operation 3.3V ±10%** differential load) of this device are a perfect match for driving high speed analog-to-digital converters. When **• Adjustable Common-Mode Output Voltage** combined with the ADC081000/ ADC081500 (single **APPLICATIONS**<br> **APPLICATIONS** or dual ADC), the LMH6555 forms an excellent 8-bit<br> **exceeding 750 MHz**<br>
exceeding 750 MHz **• Differential ADC Driver** exceeding 750 MHz.

**• Texas Instruments ADC081500/ ADC081000** The LMH6555 is offered in a space saving 16-pin

SNOSAJ1D –NOVEMBER 2006–REVISED MARCH 2013 **[www.ti.com](http://www.ti.com)**

**RUMENTS** 

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

## **ABSOLUTE MAXIMUM RATINGS (1)(2)**

(1) Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is intended to be functional, but specific performance is not ensured. For specifications, see the Electrical Characteristics tables.

(2) If Military/Aerospace specified devices are required, please contact the Texas Instruments Sales Office/ Distributors for availability and specifications.

(3) Human Body Model, applicable std. MIL-STD-883, Method 3015.7. Machine Model, applicable std. JESD22-A115-A (ESD MM std. of JEDEC)Field-Induced Charge-Device Model, applicable std. JESD22-C101-C (ESD FICDM std. of JEDEC).

## **OPERATING RATINGS (1)**

(1) Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is intended to be functional, but specific performance is not ensured. For specifications, see the Electrical Characteristics tables.

(2) The maximum power dissipation is a function of  $T_{J(MAX)}$ ,  $\theta_{JA}$  and  $T_A$ . The maximum allowable power dissipation at any ambient temperature is P<sub>D</sub>= (T<sub>J(MAX)</sub> — T<sub>A</sub>)/ θ<sub>JA</sub>. All numbers apply for package soldered directly into a 2 layer PC board with zero air flow.<br>Package should be soldered unto a 6.8 mm<sup>2</sup> copper area as shown in the "recommen

## <span id="page-2-0"></span>**3.3V ELECTRICAL CHARACTERISTICS (1)**

Unless otherwise specified, all limits are specified for T<sub>A</sub>= 25°C, V<sub>CM\_REF</sub> = 1.2V, both inputs tied to 0.3V through 50Ω(R<sub>S1</sub> &  $R_{S2}$ ) each <sup>(2)</sup>, V<sub>S</sub> = 3.3V, R<sub>L</sub> = 100Ω differential, V<sub>OUT</sub> = 0.8 V<sub>PP</sub>. See DEFINITION OF TERMS AND [SPECIFICATIONS](#page-4-0) [\(ALPHABETICAL](#page-4-0) ORDER) for definition of terms used throughout the datasheet. **Boldface** limits apply at the temperature extremes.

(1) Electrical Table values apply only for factory testing conditions at the temperature indicated. Factory testing conditions result in very limited self-heating of the device such that  $T_J = T_A$ . No specification of parametric performance is indicated in the electrical tables under conditions of internal self-heating where  $T_J > T_A$ .

(2) Quiescent device common mode input voltage is 0.3V.

(3) Limits are 100% production tested at 25°C. Limits over the operating temperature range are specified through correlation using Statistical Quality Control (SQC) methods.

(4) Typical values represent the most likely parametric norm as determined at the time of characterization. Actual typical values may vary over time and will also depend on the application and configuration. The typical values are not tested and are not ensured on shipped production material.

(5) Slew Rate is the average of the rising and falling edges.

(6) Distortion data taken under single ended input condition.

(7) 0 dBm = 894 mV<sub>PP</sub> across 100 $\Omega$  differential load

## **3.3V ELECTRICAL CHARACTERISTICS [\(1\)](#page-3-0) (continued)**

Unless otherwise specified, all limits are specified for T<sub>A</sub>= 25°C, V<sub>CM\_REF</sub> = 1.2V, both inputs tied to 0.3V through 50Ω(R<sub>S1</sub> &  $R_{S2}$ ) each <sup>[\(2\)](#page-3-0)</sup>, V<sub>S</sub> = 3.3V, R<sub>L</sub> = 100Ω differential, V<sub>OUT</sub> = 0.8 V<sub>PP</sub>. See DEFINITION OF TERMS AND [SPECIFICATIONS](#page-4-0) [\(ALPHABETICAL](#page-4-0) ORDER) for definition of terms used throughout the datasheet. **Boldface** limits apply at the temperature extremes.

<span id="page-3-0"></span>(8) Drift determined by dividing the change in parameter at temperature extremes by the total temperature change.

(9) Positive current is current flowing into the device.

(10) Total supply current is affected by the input voltages connected through  $R_{S1}$  and  $R_{S2}$ . Supply current tested with input removed.

<span id="page-10-1"></span>See DEFINITION OF TERMS AND [SPECIFICATIONS](#page-4-0) (ALPHABETICAL ORDER) for definition of terms used.

## **GENERAL**

The LMH6555 consists of three individual amplifiers:

- 1. V<sub>OUT</sub><sup>+</sup> driver
- 2. V<sub>OUT</sub><sup>−</sup> driver
- 3. The common mode amplifier

Being a differential amplifier, the LMH6555 will not respond to the common mode input (as long as it is within its input common mode range) and instead the output common mode is forced by the built-in common mode amplifier with  $V_{CM<sub>REF</sub>}$  as its input. As shown, in [Figure](#page-10-0) 23 below, the  $V_{CMO}$  output of most differential high speed ADC's is tied to the  $V_{CM,REF}$  input of the LMH6555 for direct output common mode control. In some cases, the output drive capability of the ADC V<sub>CMO</sub> output may need an external buffer, as shown, to increase its current capability in order to drive the  $V_{CM\_REF}$  pin. The Electrical [Characteristics](#page-2-0) Table shows the gain (Gain\_V<sub>CM\_REF</sub>) and the offset ( $V_{OS\_CM}$ ) from the  $V_{CM\_REF}$  to the device output common mode.

**Figure 23. Single Ended to Differential Conversion**

<span id="page-10-0"></span>The single ended input and output impedances of the LMH6555 I/O pins are close to 50Ω as specified in Electrical [Characteristics](#page-2-0) Table ( $R_{IN}$  and  $R_{O}$ ). With differential input drive, the differential input impedance  $(R<sub>IN</sub>$  <sub>DIFF</sub>) is close to 78Ω.

The device nominal input common mode voltage ( $V_{I\text{CM}}$ ) is close to 0.3V when R<sub>S1</sub> and R<sub>S2</sub> of [Figure](#page-10-0) 23 are open. Thus, the input source will experience a DC current with 0V input. Because of this, the differential output offset voltage is influenced by the matching between  $R_{S1}$  and  $R_{S2}$ . So, in a single ended input condition, if the signal source is AC coupled to one input, the undriven input needs to also be AC coupled in order to cancel the output offset voltage  $(V<sub>OOS</sub>)$ .

In applications where low output offset is required, it is possible to inject some current to the appropriate input (V<sub>IN</sub><sup>+</sup> or V<sub>IN</sub><sup>-</sup>) as an effective method of trimming the output offset voltage of the LMH6555. This is explained later in this document. The nominal value of  $R_{S1}$  and  $R_{S2}$  will also affect the insertion gain  $(A_{V\_DIFF})$ . The LMH6555 can also be used with the input AC coupled through equal valued DC blocking capacitors  $\overline{C}$ ) in series with  $V_{IN}^+$  and  $V_{IN}^-$ . In this case, the coupling capacitors need to be large enough to not block the low frequency content. The lower cutoff frequency will be  $1/(nR_{EQ}C)$ Hz with  $R_{EQ} = R_{S1} + R_{S2} + R_{INDII}$  where  $R_{INDII}$ ≈ 78Ω.

The single ended output impedance of the LMH6555 is 50Ω. The LMH6555 Electrical [Characteristics](#page-2-0) shows the device performance with 100Ω differential output load, as would be the case if a device such as the ADC081000/ ADC081500 (single/ dual ADC) were being driven.

**EXAS NSTRUMENTS** 

## **CIRCUIT ANALYSIS**

[Figure](#page-11-0) 24 shows the block diagram of the LMH6555.

<span id="page-11-0"></span>The differential input stage consists of cross-coupled common base bipolar NPN stages, Q1 and Q2. These stages give the device its differential input characteristic. The internal loop gain from  $V_x$  and  $V_y$  internal nodes (Q1 and Q2 emitters) to the output is large, such that these nodes act as a virtual ground. The cross-coupling will ensure that these nodes are at the same voltage as long as the amplifier is operating within its normal range. Output common mode voltage is enforced through the action of "A<sub>CM</sub>" which servos the output common mode to the " $V_{CM~REF}$ " input voltage.

**The discussion that follows, provides the formulas needed to analyze single ended and differential input applications. For a more detailed explanation including derivations, please see [Appendix](#page-26-0) at the end of the datasheet.**

## **SINGLE-ENDED INPUT**

The following is the procedure for determining the device operating conditions for single ended input applications. This example will use the schematic shown in [Figure](#page-12-0) 25.

### **Figure 25. Single-Ended Input Drive**

<span id="page-12-0"></span>1. Determine the driven input's (V<sub>IN</sub>+ or V<sub>IN</sub>−) swing knowing that each input common mode impedance to ground ( $R<sub>IN</sub>$ ) is 50Ω:

 $V_{\text{IN}}$ + (or  $V_{\text{IN}}$ -) =  $V_{\text{IN}}$  · R<sub>IN</sub>/(R<sub>IN</sub> + R<sub>S</sub>) (1)

#### For [Figure](#page-12-0) 25:

 $VIN + = 0.3 \text{ VPP} \cdot 50/(50+50) = 0.15 \text{ VPP}$  (2)

2. Calculate  $V_{\text{OUT}}$  knowing the Insertion Gain (A<sub>V DIFF</sub>):

 $R_F = 430\Omega$ 

 $R_{\text{IN}}$  DIFF = 78 $\Omega$  (3)

For [Figure](#page-12-0) 25:

 $R_S = 50\Omega \rightarrow A_{V\text{ DIFF}} = 4.83 \text{ V/V}$  $V_{\text{OUT}} = (0.3 \text{ V}_{\text{PP}}/2) \cdot 4.83 \text{ V/V} = 724.5 \text{ mV}_{\text{PP}}$  (4)

3. Determine the peak-to-peak differential current  $(I_{IN\_DIFF})$  through the device's differential input impedance  $(R_{IN\ DIFF})$  which would result in the V<sub>OUT</sub> calculated in step 2:  $I_{\text{IN}}$   $_{\text{DIF}} = V_{\text{OUT}}/ R_{\text{F}}$  (5)

For [Figure](#page-12-0) 25:

 $I_{IN\_DIFF} = 724.5 \text{ mV}_{PP} / 430\Omega = 1.685 \text{ mA}_{PP}$  (6)

4. Determine the swing across the input terminals ( $V_{IN\ DIFF}$ ) which would give rise to the I<sub>IN DIFF</sub> calculated in step 3 above.

 $V_{\text{IN}}$  diff =  $I_{\text{IN}}$  diff  $\cdot$  R<sub>IN</sub> diff  $\cdot$  R<sub>IN</sub> different to  $(7)$ 

For [Figure](#page-12-0) 25:

 $V_{\text{IN}}$  DIFF = 1.685 mA<sub>PP</sub> · 78 $\Omega$  = 131.4 mV<sub>PP</sub> (8)

5. Calculate the undriven input's swing, based on  $V_{IN\_DIFF}$  determined in step 4 and  $V_{IN}+$  calculated in step 1:  $V_{\text{IN}} = V_{\text{IN}} + - V_{\text{IN}}$  different substitutions of the value of  $(9)$ 

SNOSAJ1D –NOVEMBER 2006–REVISED MARCH 2013 **[www.ti.com](http://www.ti.com)**

**RUMENTS** 

For [Figure](#page-12-0) 25:  $V_{\text{IN}}$  = 150 mV<sub>PP</sub> - 131.4 mV<sub>PP</sub> = 18.6 mV<sub>PP</sub> (10)

6. Determine the DC average of the two inputs  $(V_{I \text{ CM}})$  by using the following expression:

 $V_{I\_CM}$  = 12.6 mA  $\cdot$  R<sub>E</sub>  $\cdot$  R<sub>S</sub> / (R<sub>S</sub> + R<sub>G</sub> + R<sub>E</sub>)

where

- $R_F = 25\Omega$
- $R_G = 39\Omega$  (both internal to the LMH6555)

For Figure 25  
\n
$$
R_s = 50\Omega \rightarrow V_{LCM} = 15.75 / (R_s + 64)
$$
 (11)

$$
V_{1\_CM} = 15.75 / (50 + 64) = 138.2 \text{ mV}
$$
\n(12)

The values determined with the procedure outlined here are shown in [Figure](#page-13-0) 26.

**Figure 26. Input Voltage for [Single-Ended](#page-12-0) Input Drive Schematic**

## <span id="page-13-0"></span>**DIFFERENTIAL INPUT**

The following is the procedure for determining the device operating conditions for differential input applications using the [Figure](#page-13-1) 27 schematic as an example.

Assuming transformer secondary,  $V_{IN}$ , of 300 m $V_{PP}$ 

## **Figure 27. Differential Input Drive**

<span id="page-13-1"></span>1. Calculate the swing across the input terminals ( $V_{IN\_DIFF}$ ) by considering the voltage division from the differential source  $(V_{\text{IN}})$  to the LMH6555 input terminals with differential input impedance  $R_{\text{IN}}$  DIFF:  $V_{\text{IN}}$  DIFF =  $V_{\text{IN}} \cdot R_{\text{IN}}$  DIFF/ (2Rs + R<sub>IN</sub> DIFF) (13)

For [Figure](#page-13-1) 27:

 $V_{\text{IN}}$  DIFF = 300 mV<sub>PP</sub> · 78 / (100 + 78) = 131.5 mV<sub>PP</sub> (14)

**[www.ti.com](http://www.ti.com)** SNOSAJ1D –NOVEMBER 2006–REVISED MARCH 2013

The values determined with the procedure outlined here are shown in [Figure](#page-14-0) 28.

 $V_{OUT} = (0.3 V_{PP}/2) \cdot 4.83 V/V = 724.5 mV_{PP}$  (19)

<span id="page-14-0"></span>**Figure 28. Input Voltage for [Figure](#page-13-1) 27 Schematic**

## **SOURCE IMPEDANCE(S) AND THEIR EFFECT ON GAIN AND OFFSET**

The source impedances  $R_{S1}$  and  $R_{S2}$ , as shown in [Figure](#page-13-1) 25 or Figure 27, affect gain and output offset. The Electrical [Characteristics](#page-2-0) and TYPICAL PERFORMANCE [CHARACTERISTICS](#page-6-0) are generated with equal valued source impedances  $R_{S1}$  and  $R_{S2}$ , unless otherwise specified. Any mismatch between the values of these two impedances would alter the gain and offset voltage.

## **OUTPUT OFFSET CONTROL AND ADJUSTMENT**

There are applications which require that the LMH6555 differential output voltage be set by the user. An example of such an application is a unipolar signal which is converted to a differential output by the LMH6555. In order to utilize the full scale range of the ADC input, it is beneficial to shift the LMH6555 outputs to the limits of the ADC analog input range under minimal signal condition. That is, one LMH6555 output is shifted close to the negative limit of the ADC analog input and the other close to the positive limit of the ADC analog input. Then, under maximum signal condition, with proper gain, the full scale range of the ADC input can be traversed and the ADC input dynamic range is properly utilized. If this forced offset were not imposed, the ADC output codes would be reduced to half of what the ADC is capable of producing, resulting in a significant reduction in ENOB. The choice of the direction of this shift is determined by the polarity of the expected signal.

Another scenario where it may be necessary to shift the LMH6555 output offset voltage is in applications where it is necessary to improve the specified Output Offset Voltage (differential mode), " $V_{OOS}$ ". Some ADC's, including the ADC081000/ ADC081500 (and their dual counterparts), have internal registers to correct for the driver's (LMH6555)  $V_{\text{OOS}}$ . If the LMH6555  $V_{\text{OOS}}$  rating exceeds the maximum value allowed into this register, then shifting the output is required for maximum ADC performance.

It is possible to affect output offset voltage by manipulating the value of one input resistance relative to the other (e.g.  $R_{S1}$  relative to  $R_{S2}$  or vice versa). However, this will also alter the gain. Assuming that the source is applied to the  $\rm{V_{IN}}^*$  side through R<sub>S1</sub>, [Figure](#page-15-0) 29(A) shows the effect of varying R<sub>S1</sub> on the overall gain and output offset voltage. [Figure](#page-15-0) 29(B) shows the same effects but this time for when the undriven side impedance,  $R_{S2}$ , is varied.

**Figure 29. Gain & Output Offset Voltage vs. Source Impedance Shift for Single Ended Input Drive**

<span id="page-15-0"></span>As can be seen in [Figure](#page-15-0) 29, the source impedance of the input side being driven has a bigger effect on gain than the undriven source impedance.  $R_{S1}$  and  $R_{S2}$  affect the output offset in opposite directions. Manipulating the value of  $R_{S2}$  for offset control has another advantage over doing the same to  $R_{S1}$  and that is the signal input termination is not affected by it. This is especially important in applications where the signal is applied to the LMH6555 through a transmission line which needs to be terminated in its characteristic impedance for minimum reflection.

For reference, [Figure](#page-16-0) 30 shows the effect of source impedance misbalance on overall gain and output offset voltage with differential input drive.

**Figure 30. Gain & Output Offset Voltage vs. Source Impedance Shift for Differential Input Drive**

<span id="page-16-0"></span>It is possible to manipulate output offset with little or no effect on source resistance balance, gain, and, cable termination.

**Figure 31. Differential Output Shift Circuits**

<span id="page-16-1"></span> $R_X$ , shown in [Figure](#page-16-1) 31(a) and Figure 31(b), injects current into the input to achieve the required output shift. For a positive shift, positive current would need to be injected into the  $\vee_{\mathsf{IN}}{}^+$  terminal ([Figure](#page-16-1) 31*(a)*) and for a negative shift, to the V<sub>IN</sub> $^-$ terminal ([Figure](#page-16-2) 31*(b)*). Figure 32 shows the effect of R<sub>X</sub> on the output with V<sub>X</sub> = 3.3V or 5V, and  $R_{S1} = R_{S2} = 50Ω$ .

<span id="page-16-2"></span>**Figure 32. LMH6555 Differential Output Shift Due to R<sup>X</sup> in [Figure](#page-16-1) 31**

To shift the LMH6555 differential output negative by about 100 mV, referring to the plot in [Figure](#page-16-2) 32,  $R_x$  would be chosen to be around 3.9 kΩ in the schematic of [Figure](#page-16-1) 31(b) (using  $V_x = V_s = 3.3V$ ).

In applications where V<sub>IN</sub> has a built-in non-zero offset voltage, or when R<sub>S1</sub> and R<sub>S2</sub> are not 50Ω, the [Figure](#page-16-2) 32 plot cannot be used to estimate the required value for  $R_X$ .

Consider the case of a more general offset correction application, shown in [Figure](#page-17-0) 33(a), where R<sub>S1</sub> = R<sub>S2</sub> = 75 $\Omega$ and V<sub>IN</sub> has a built-in offset of −50 mV. It is necessary to shift the differential output offset voltage of the LMH6555 to 0 mV. [Figure](#page-17-0) 33(b) is the Thevenin equivalent of the circuit in Figure 33(a) assuming  $R_x \gg R_{S2}$ .

(20) The expression derived for V<sub>OUT</sub> in [Equation](#page-17-1) 20 can be set equal to zero to solve for R<sub>X</sub> resulting in R<sub>X</sub> = 4.95 kΩ. If the differential output offset voltage, V<sub>OOS</sub>, is also known, V<sub>OUT</sub> could be set to a value equal to –V<sub>OOS</sub>. For example, if the  $V_{OOS}$  for the particular LMH6555 is +30 mV, then the following nulls the differential output:

**Figure** 33. Offset Correction Example  $(R_S = 75\Omega)$ 

From the gain expression in [Equation](#page-30-0) 44 (see [Appendix\)](#page-26-0) (but with opposite polarity because  $V_{TH}$  is applied to

$$
V_{\text{OUT}} = -30 \text{ mV} = (-1.89) \left( -50 \text{ mV} + \frac{248}{R_{\text{X}}} \right)
$$
  

$$
\Rightarrow R_{\text{X}} = 3.76 \text{ k}\Omega
$$
 (21)

<span id="page-17-3"></span><span id="page-17-2"></span> $R_X$  >>  $R_{S2}$  confirming the assumption made in the derivation. Note that [Equation](#page-17-2) 21, which is derived based on the configuration in [Figure](#page-16-1) 31(b), will yield a real solution for  $R_X$  if and only if:

 $V_{OOS} \geq (V_{IN} \text{ OFFSET} \times 1.89)$ 

 $\frac{114}{2R_s + 78}$   $\Rightarrow$ 

For [Figure](#page-16-1) 31(b) and with  $R_s = 75Ω$ 

©  $V_{\text{OUT}} = \frac{-430\Omega}{(1.00 \text{ m/s}^2)(1.00 \text{ m/s}^2)} \times (-50 \text{ m/s} + \frac{75}{R})$  $\frac{10032}{(150 + 78)\Omega}$  x

where

 $\mathsf{V}_{\mathsf{OUT}}$  $\frac{V_{\text{OUT}}}{V_{\text{TH}}} = \frac{-R_{\text{F}}}{2R_{\text{S}} + 1}$ 

<span id="page-17-1"></span>V<sub>IN</sub><sup>-</sup> instead):

<span id="page-17-0"></span>(a)

 $V_{\text{IN OFFSET}}$  is the source offset shown as −50 mV in [Figure](#page-17-0) 33(a) (22)

® ® ©

 $\left(-50 \text{ mV} + \frac{18}{R_{\text{X}}} 3.3 \text{V}\right)$ 

If [Equation](#page-17-3) 22 were not satisfied, then [Figure](#page-16-1) 31(a) offset correction, where R<sub>X</sub> is tied to the V<sub>IN</sub><sup>+</sup> side, should be employed instead.

Alternatively, replace the  $V_X$  and  $R_X$  combination with a discrete current source or current sink. Because of a current source's high output impedance, there will be less gain imbalance. However, a current source might have a relatively large output capacitance which could degrade high frequency performance.

## **INTERFACE DESIGN EXAMPLE**

As shown in [Figure](#page-18-0) 34 below, the LMH6555 can be used to interface an open collector output device (U1) to a high speed ADC. In this application, the LMH6555 performs the task of amplifying and driving the 100Ω differential input impedance of the ADC.

V<sub>CM\_REF</sub> buffer not shown

**Figure 34. Differential Amplification and ADC Drive**

<span id="page-18-0"></span>For applications similar to the one shown in [Figure](#page-18-0) 34, the following conditions should be maintained:

- 1. The LMH6555 differential output voltage has to comply with the ADC full scale voltage (800 mV<sub>PP</sub> in this case).
- 2. The LMH6555 input Common Mode Voltage Range is observed. "CMVR", as specified in [Electrical](#page-2-0) [Characteristics](#page-2-0), is to be between −0.3V and 2.0V for the specified CMRR.
- 3. U1 collector voltage swing must to be observed so that the U1 output transistors do not saturate. The expected operating range of these output transistors is defined by the specifications and operating conditions of U1.

Consider a numerical example (R<sub>L</sub> refers to R<sub>L1</sub> & R<sub>L2</sub>, R<sub>S</sub> refers to R<sub>S1</sub> & R<sub>S2</sub>).

Assume:

 $V_{CC}$  = 10V, U1 peak-to-peak collector current (I<sub>PP</sub>) = 15 mA<sub>PP</sub> with 10 mA quiescent (I<sub>cQ</sub>), and minimum operational U1 collector voltage = 6V.

Here are the series of steps to take in order to carry out this design:

a. Select the R<sub>L</sub> value which allows compliance with the U1 collector voltage (6V in this case) with 1V extra as margin because of LMH6555 loading.

 $R_{L} = [10 - (6+1)]$  V / (10+ 7.5) mA = 171 $\Omega$ 

Choose 169Ω, 1% resistors for  $R_1$ 

b. Find the value of  $R_S$  to get the proper swing at the output (800 mV<sub>PP</sub>). To do so, convert the input stage into its Norton equivalent as shown in [Figure](#page-19-0) 35

### **Figure 35. Norton Equivalent of the Input Circuitry Tied to Q1 within the LMH6555 in [Figure](#page-18-0) 34**

<span id="page-19-0"></span> $I_N = I_N$  (common mode) +  $I_N$  (differential)  $I_N$  (common mode) = (V<sub>CC</sub> – I<sub>cQ</sub> \* R<sub>L</sub>) / (R<sub>L</sub> + R<sub>S</sub> + R<sub>G</sub>)  $I_N$  (differential) =  $I_{PP}$  \* R<sub>L</sub> / (R<sub>L</sub> + R<sub>S</sub> + R<sub>G</sub>) (23)

The entirety of the Norton source differential component will flow through the feedback resistors within the LMH6555 and generate an output. Therefore:

$$
R_{\rm N} \text{ (differential)}^{\text{ in } R} R_{\rm F} = 800 \text{ mV}_{\rm PP}
$$
\n
$$
\rightarrow R_{\rm S} = (R_{\rm L}^* \, I_{\rm PP}^* \, R_{\rm F} / 0.8) - R_{\rm G} - R_{\rm L}
$$
\nwhere

\n\n- $R_{\rm F} = 430 \Omega$
\n- $R_{\rm G} = 39 \Omega \, (R_{\rm F} \text{ and } R_{\rm G} \text{ are internal LMH6555 resistances)$
\n
\nSo, in this case:

\n
$$
R_{\rm S} = (169 * 15 \text{ mA}_{\rm PP} * 430 / 0.8) - 39 - 169 = 1154 \Omega
$$
\n\n- Choose 1.15 kΩ, 1% resistors for R<sub>S</sub>
\n- With R, and R<sub>S</sub> defined ensure that the I11 collector voltane(s) minimum is not violated due to the loading
\n

c. With R<sub>L</sub> and R<sub>S</sub> defined, ensure that the U1 collector voltage(s) minimum is not violated due to the loading effect of the LMH6555 through R<sub>S</sub>. Also, it is important to ensure that the LMH6555's CMVR is also not violated.

The "V<sub>x</sub>" node voltage within the LMH6555 (see [Figure](#page-19-0) 35) would need to be calculated. Use the Common Mode component of the Norton equivalent source from above, and write the KCL at the  $V_x$  node as follows:

$$
V_x / R_E + V_x / R_N = 12.6 \text{ mA} + I_N \text{ (common mode)}; \text{ with } R_E = 25\Omega
$$
  
\n $V_x / R_E + V_x / R_N = 12.6 \text{ mA} + (V_{CC} - I_{cQ} R_L) / (R_L + R_S + R_G)$   
\n $\rightarrow V_x = 0.4595V$  (26)

With  $V_x$  calculated, both the input voltage range (high and low) and the low end of the U1 collector voltage  $(V<sub>C</sub>)$  can be derived to be within the acceptable range. If necessary, steps "a" through "c" would have to be repeated to readjust these values.

$$
V_{C} = V_{X} R_{L} / R_{N} + I_{N} (R_{S} + R_{G})
$$
\n(27)

 $I_{N_{\text{L}}}$ High = 7.05 mA,  $I_{N_{\text{L}}}$  Low = 5.19 mA (based on the values derived)  $\rightarrow$  V<sub>C</sub>\_High = 0.4595 \* 169 / 1358 + 7.05 mA (1150 + 39) = 8.44V  $\rightarrow$  V<sub>C</sub>\_Low = 0.4595 \* 169 / 1358 + 5.19 mA (1150 + 39) = 6.22V (28)

 $I = I H + R$ 

$$
V_{IN} = V_X (R_N - R_G) / R_N + I_N R_G
$$
  
\n
$$
\rightarrow V_{IN} - High = 0.4595 * (1358 - 39) / 1358 + 7.05 mA * 39 = 0.721 V
$$
  
\n
$$
\rightarrow V_{IN} - Low = 0.4595 * (1358 - 39) / 1358 + 5.19 mA * 39 = 0.649 V
$$
 (29)

[Figure](#page-20-0) 36 shows the complete solution using the values derived above, with the node voltages marked on the schematic for reference.

<span id="page-20-0"></span>It is important to note that the matching of the resistors on either input side of the LMH6555 ( $R_{S1}$  to  $R_{S2}$  and  $R_{L1}$ to  $R_{12}$ ) is very important for output offset voltage and gain balance. This is particularly true with values of  $R_S$ higher than the nominal 50Ω. Therefore, in this example, 1% or better resistor values are specified.

If the U1 collector voltage turns out to be too low due to the loading of the LMH6555, lower  $R_L$ . Lower values of  $R_L$  result in lower  $R_S$  which in turn increases the LMH6555's V<sub>LCM</sub> because of increased pull up action towards  $\rm V_{\rm CC}^-$ . The upper limit on  $\rm V_{\rm l\,CM}$  is 2V. [Figure](#page-20-1) 37 shows the 2<sup>nd i</sup>mplementation of this same application with lowered values of  $R_L$  and  $R_S$ . Notice that the lower end of U1's collector voltage and the upper end of LMH6555's  $V_{\text{LCM}}$  have both increased compared to the 1<sup>st</sup> implementation.

**Figure 37. Implementation #2 of [Figure](#page-18-0) 34 Design Example**

<span id="page-20-1"></span>An alternative would be to AC couple the LMH6555 inputs. With this approach, the design steps would be very similar to the ones outlined except that there would be no common mode interaction between the LMH6555 and U1 and this results in fewer design constraints:

 $V_x / R_E = 12.6 \text{ mA} \rightarrow V_x = 0.3150 \text{ V}$  (30)

**RUMENTS** 

SNOSAJ1D –NOVEMBER 2006–REVISED MARCH 2013 **[www.ti.com](http://www.ti.com)**

For the component values shown in [Figure](#page-20-1) 37 use:

1.  $V_{C_{-}}$ High =  $V_{CC} - R_{L} (I_{cQ} + I_{PP} / 2 - I_{N} (differential) / 2)$  $V_{C_{\text{c}}}\text{Low} = V_{CC} - R_{\text{L}} (l_{cQ} - l_{\text{PP}} / 2 + l_{\text{N}} \text{ (differential) / 2)}$  (31)

 $I_N$  (differential) =  $I_{PP}$  \* R<sub>L</sub> / (R<sub>L</sub> + R<sub>S</sub> + R<sub>G</sub>) = 1.88 mA (based on the values used.)  $\rightarrow$  V<sub>C</sub>\_High = 10 – 80.6 (10 + 15 / 2 – 1.88 /2) mA = 8.67V  $\rightarrow$  V<sub>C</sub>\_Low = 10 – 80.6 (10 – 15 / 2 + 1.88 /2) mA = 9.72V (32)

 $V_{IN} = V_X \pm R_G$ . I<sub>N</sub> (differential) /2  $\rightarrow$  V<sub>IN</sub> High = 0.3150 + 39  $*$  1.88 mA /2 = 0.3517V

 $\rightarrow$ V<sub>IN</sub>\_Low = 0.3150 - 39 \* 1.88 mA /2 = 0.2783V (33)

[Figure](#page-21-0) 38 shows the AC coupled implementation of the [Figure](#page-20-1) 37 schematic along with the node voltages marked to demonstrate the reduced  $V_{ICM}$  of the LMH6555 and the increase in the U1 collector voltage minimum.

**Figure 38. AC Coupled Version of [Figure](#page-20-1) 37**

<span id="page-21-0"></span>Note that the lower cut-off frequency is:

 $f_{\text{out-off}} = 1 / (\pi \text{Req} C_{\text{S}})$  where Req = R<sub>S1</sub>+ R<sub>S2</sub> + R<sub>IN</sub> <sub>DIFF</sub> where R<sub>IN</sub> DIFF ≈ 78 $\Omega$  (34)

So, for the component values shown ( $C_S = 0.01 \mu F$  and  $R_{S1} = R_{S2} = 523 \Omega$ ): f\_cut-off = 28.2 kHz (35)

## **DATA ACQUISITION APPLICATIONS**

[Figure](#page-22-0) 39 shows the LMH6555 used as the differential driver to the Texas Instruments ADC081500 running at 1.5G samples/second.

**Figure 39. Schematic of the LMH6555 Interfaced to the ADC081500**

<span id="page-22-0"></span>In the schematic of [Figure](#page-22-0) 39, the LMH6555 converts a single ended input into a differential output for direct interface to the ADC's 100Ω differential input. An alternative approach to using the LMH6555 for this purpose, would have been to use a balun transformer, as shown in [Figure](#page-22-1) 40.

<span id="page-22-1"></span>In the circuit of [Figure](#page-22-1) 40, the ADC will see a 100Ω differential driver which will swing the required 800 mV<sub>PP</sub> when V<sub>IN</sub> is 1.6 V<sub>PP</sub>. The source (V<sub>IN</sub>) will see an overall impedance of 200Ω for the frequency range that the transformer is specified to operate. Note that with this scheme, the signal to the ADC must be AC coupled, because of the transformer's minimum operating frequency which would prevent DC coupling. For the transformer specified, the lower operating frequency is around 4.5 MHz and the input high pass filter's −3 dB bandwidth is around 340 kHz for the values shown (or (1/ $\pi R_{EQ}C$ )Hz where  $R_{EQ} = 200\Omega$ ).

[Table](#page-23-0) 1 compares the LMH6555 solution [\(Figure](#page-22-0) 39) vs. that of the balun transformer coupling [\(Figure](#page-22-1) 40) for various categories.

<span id="page-23-0"></span>

## **Table 1. ADC Input Coupling Schemes Compared**

## **GAIN FLATNESS**

In applications where the full 1.2 GHz bandwidth of the LMH6555 is not necessary, it is possible to improve the gain flatness frequency at the expense of bandwidth. [Figure](#page-23-1) 41 shows  $\textsf{C}_{\textsf{O}}$  placed across the LMH6555 output terminals to reduce the frequency response gain peaking and thereby to increase the ±0.5 dB gain flatness frequency.

**Figure** 41. Increasing ±0.5 dB Gain Flatness using External Output Capacitance, C<sub>O</sub>

<span id="page-23-1"></span>[Figure](#page-24-0) 42, [Figure](#page-24-1) 43, and and [Figure](#page-24-2) 44 show the FFT analysis results with the setup shown in [Figure](#page-22-0) 39.

<span id="page-24-0"></span>**Figure 42. LMH6555 FFT Result When Used as the Differential Driver to ADC081500**

<span id="page-24-1"></span>**Figure 43. LMH6555 FFT Result When Used as the Differential Driver to ADC081500 (Lower Fs/2 Region Magnified)**

<span id="page-24-2"></span>**Figure 44. LMH6555 FFT Result When Used as the Differential Driver to ADC081500 (Upper Fs/2 Region Magnified)**

[Figure](#page-24-0) 42, [Figure](#page-24-1) 43, and [Figure](#page-24-2) 44 information summary:

- Fundamental Test Frequency 744 MHz
- LMH6555 Output  $0.8$  V<sub>PP</sub>
- Sampling Rate: 1.5G samples/second
- 2nd Harmonic: −59 dBc @ ∼ 12 MHz or |1.5 GHz\*1– 744 MHz\*2|
- 3rd Harmonic: −57 dBc @ ∼ 732 MHz or |1.5 GHz\*1- 744 MHz \*3|
- 4th Harmonic −71 dBc @ ∼ 24 MHz or |1.5 GHz\*2 744 MHz \*4|
- 5th Harmonic −68 dBc @ ∼ 720 MHz or |1.5 GHz\*2- 744 MHz\*5|
- 6th Harmonic −68 dBc @ ∼ 36 MHz or |1.5 GHz\*3- 744 MHz\*6|
- THD −51.8 dBc
- SNR 43.4 dB
- Spurious Free Dynamic
- Range (SFDR): 57 dB
- SINAD 42.8 dB
- ENOB 6.8 bits

The LMH6555 is capable of driving a variety of Texas Instruments Analog to Digital Converters. This is shown in [Table](#page-25-0) 2, which offers a complete list of possible signal path ADC+ Amplifier combinations. The use of the LMH6555 to drive an ADC is determined by the application and the desired sampling process (Nyquist operation, sub-sampling or over-sampling). See application note AN-236 ([SNAA079\)](http://www.ti.com/lit/pdf/SNAA079) for more details on the sampling processes and application note AN-1393 [\(SNOA461](http://www.ti.com/lit/pdf/SNOA461)) for details on "Using High Speed Differential Amplifiers to Drive ADCs". For more information regarding a particular ADC, refer to the particular ADC datasheet for details.

<span id="page-25-0"></span>

## **EXPOSED PAD WQFN PACKAGE**

The LMH6555 is in a thermally enhanced package. The exposed pad (device bottom) is connected to the GND pins. It is recommended, but not necessary, that the exposed pad be connected to the supply ground plane. The thermal dissipation of the device is largely dependent on the connection of this pad. The exposed pad should be attached to as much copper on the circuit board as possible, preferably external copper. However, it is very important to maintain good high speed layout practices when designing a system board.

Here is a link to more information on the Texas Instruments 16-pin WQFN package:

<http://www.ti.com/packaging>

## **EVALUATION BOARD**

Texas Instruments suggests the following evaluation board as a guide for high frequency layout and as an aid in device testing and characterization.

The evaluation board can be ordered when a device sample request is placed with Texas Instruments.

## <span id="page-26-0"></span>**Appendix**

Here is a more detailed analysis of the LMH6555, including the derivation of the expressions used throughout APPLICATION [INFORMATION](#page-10-1).

### **INPUT STAGE**

Because of the input stage cross-coupling, if the instantaneous values of the input node voltages ( $V_{IN}^+$  and  $V_{IN}^-$ ) and current values are required, use the circuit of [Figure](#page-26-1) 45 as the equivalent input stage for each input (V<sub>IN</sub><sup>+</sup> and  $V_{IN}^-$ ).

**Figure 45. Equivalent Input Stage**

<span id="page-26-1"></span>Using this simplified circuit, one can assume a constant collector current, to simplify the analysis. This is a valid approximation as the large open loop gain of the device will keep the two collector currents relatively constant. First derive Q1 and Q2 emitter voltages. From there, derive the voltages at  $V_{IN}^+$  and  $V_{IN}^-$ .

With the component values shown, it is possible to analyze the input circuits of [Figure](#page-26-1) 45 in order to determine Q1 and Q2 emitter voltages. This will result in a first order estimate of Q1 and Q2 emitter voltages. Since Q1 and Q2 emitters are cross-coupled, the voltages derived would have to be equal. With the action of the common mode amplifier, "A<sub>CM</sub>", shown in [Figure](#page-11-0) 24, these two emitters will be equalized. So, one other iteration can be performed whereby both emitters are set to be equal to the average of the 1<sup>st</sup> derived emitter voltages. Using this new emitter voltage, one could recalculate  $V_{\text{IN}}{}^+$  and  $V_{\text{IN}}{}^-$  voltages. The values derived in this fashion will be within ±10% of the measured values.

## **Single Ended Input Analysis**

Here is an actual example to further clarify the procedure.

Consider the case where the LMH6555 is used as a single ended to differential converter shown in [Figure](#page-27-0) 46.

**Figure 46. Single Ended Input Drive**

<span id="page-27-0"></span>The first task would be to derive the internal transistor emitter voltages based on the schematic of [Figure](#page-26-1) 45 (assuming that there is no interaction between the stages.) Here is the derivation of  $V_X$  and  $V_{y}$ :

$$
\frac{Vx}{25} + \frac{Vx \pm 0.15}{89} = 12.6 \text{ mA} \Rightarrow Vx = \begin{cases} 0.279V \\ 0.213V \end{cases}
$$
  

$$
\frac{Vy}{25} + \frac{Vy}{89} = 12.6 \text{ mA} \Rightarrow Vy = 0.246V
$$
 (36)

 $V_X$  varies with  $V_{IN}$ <sup>+</sup> (0.213V with negative  $V_{IN}$  swing and 0.279V with positive.) The values derived above assume that the two halves of the input circuit do not interact with each other. They do through the common mode amplifier and the input stage cross-coupling.  $\mathsf{V}_\mathsf{x}$  and  $\mathsf{V}_\mathsf{y}$  are equal to the average of  $\mathsf{V}_\mathsf{y}$  with either end of the swing of V<sub>X</sub>. This is calculated below along with the derivation of V<sub>IN</sub><sup>+</sup> and V<sub>IN</sub><sup>-</sup> based on this new average emitter voltage (the average of  $\mathsf{V}_{\mathsf{X}}$  and  $\mathsf{V}_{\mathsf{y}}$ .)

$$
\frac{Vx + Vy}{2} = \begin{cases} 0.279 + 0.246 \\ 2 \end{cases} = 0.262V
$$
  
= Voltage  
Swing  

$$
V_{IN}^+ = \pm 0.15V - 50
$$
  

$$
V_{IN}^+ = \frac{0.213V}{63.2 \text{ mV}}; \quad V_{IN} = \frac{50}{89} \times \frac{0.262V}{0.229V}
$$
  

$$
V_{IN}^+ = \begin{cases} 0.213V \\ 63.2 \text{ mV} \end{cases}; \quad V_{IN} = \frac{50}{89} \times \frac{0.262V}{0.229V}
$$
  

$$
V_{IN} = \begin{cases} 0.147V \\ 0.129V \end{cases}
$$
 (37)

With 0.3 V<sub>PP</sub> V<sub>IN</sub>, V<sub>IN</sub><sup>+</sup> experiences 150 mV<sub>PP</sub> (213 mV - 63.2 mV) of swing and V<sub>IN</sub><sup>-</sup> will swing by about 18.6 mV<sub>PP</sub> in the process (147 mV – 129 mV). The input voltages are shown in [Figure](#page-27-1) 47.

<span id="page-27-1"></span>

Using the calculated swing on  $V_{IN}^+$  with known  $V_{IN}$ , one can estimate the input impedance,  $R_{IN}$  as follows:

$$
R_{IN} = \frac{\Delta V_{IN}^{+}}{\Delta I_{IN}^{+}} = \frac{150 \text{ mV}}{(-1.26 + 4.26) \text{ mA}} = 50 \Omega
$$
\n(38)

#### **Differential Input Analysis**

Assume that the LMH6555 is used as a differential amplifier with a transformer with its Center Tap at ground as shown in [Figure](#page-28-0) 48:

Assuming transformer secondary,  $V_{IN}$ , of 300 m $V_{PP}$ 

#### **Figure 48. Differential Input Drive**

<span id="page-28-0"></span>The input voltages  $(V_{IN}^+$  and  $V_{IN}^-)$  can be derived using the technique explained previously. Assuming no transformer output and referring to the schematic of [Figure](#page-26-1) 45:

$$
\frac{Vx}{25} + \frac{Vx}{50 + 39} = 12.6 \text{ mA} \Rightarrow Vx = Vy = 0.246V
$$
  

$$
V_{IN}^+ = \frac{50}{50 + 39} \times 0.246 \Rightarrow V_{IN}^+ = V_{IN} = 0.138V
$$
 (39)

The peak  $V_{IN}$ <sup>+</sup> and  $V_{IN}$ <sup>-</sup> voltages can be determined using the transformer output voltage. Assuming there is 0.3 V<sub>PP</sub> of signal across the transformer secondary, 1/2 of that, or 0.15 V<sub>PP</sub> (±75 mV peak), would appear at each input side (V<sub>1</sub> or V<sub>2</sub> in [Figure](#page-28-0) 48). Here is the derivation of the LMH6555 input terminal's peak voltages.

$$
\frac{Vx}{25} + \frac{Vx \pm 0.075}{89} = 12.6 \text{ mA} \Rightarrow Vx = \begin{cases} 262.4 \text{ mV} \\ 229.5 \text{ mV} \end{cases}
$$
(40)

When  $V_1$  swings positive,  $V_2$  will go negative by the same value, and vice versa. Therefore, the values derived above for  $V_x$  can be used to determine the average emitter voltage, as described earlier:

$$
\frac{Vx + Vy}{2} = \frac{262.4 \text{ mV} + 229.5 \text{ mV}}{2} = 245.9 \text{ mV} = \frac{\text{Emitter}}{\text{Voltage}}
$$
  

$$
V_{1N}^+ = \pm 75 \text{ mV} - 50 \frac{\pm 75 \text{ mV} - 245.9 \text{ mV}}{89}
$$
  

$$
V_{1N}^+ = \begin{cases} 171.0 \text{ mV} \\ 105.3 \text{ mV} \end{cases}
$$
 and by symmetry:  $V_{1N}^- = \begin{cases} 105.3 \text{ mV} \\ 171.0 \text{ mV} \end{cases}$ 

With the transformer voltage of 0.3 V<sub>PP</sub>, each input (V<sub>IN</sub><sup>+</sup> and V<sub>IN</sub><sup>-</sup>) swings from 105.3 mV to 171.0 mV or about 65.7 m $V_{\text{PP}}$ . The input voltages are shown in [Figure](#page-29-0) 49.

(41)

(42)

**Figure 49. Input Voltages for [Figure](#page-28-0) 48 Schematic**

<span id="page-29-0"></span>Knowing the device input terminal voltages, one can estimate the differential input impedance as follows:

 $R_{\mathsf{IN\_DIFF}}$  $R_{\text{IN\_DIFF}} + 100$  = 0.131 V<sub>PP</sub>  $\frac{1}{0.3 \text{ V}_{PP}} \Rightarrow R_{\text{IN\_DIFF}} = 78\Omega$ 

This is comparable to  $R_{IN-DIFF}$  found in Electrical [Characteristics.](#page-2-0)

## **OUTPUT STAGE AND GAIN ANALYSIS**

Differential gain is determined by the differential current flow through the feedback resistors  $R_{F1}$  and  $R_{F2}$  as shown in [Figure](#page-11-0) 24. Current through R<sub>F1</sub> (or R<sub>F2</sub>) sets the V<sub>OUT</sub> (or V<sub>OUT</sub><sup>+</sup>) swing. The nominal value of these resistors is close to 430Ω.

The LMH6555 output stage consists of two bipolar common emitter amplifiers with built in output resistances,  $R_{T1}$ and R<sub>T2</sub>, of 50Ω, as shown in [Figure](#page-29-1) 50.

**Figure 50. Output Stage Including External Load R<sup>L</sup>**

<span id="page-29-1"></span>With an output differential load, R<sub>L</sub>, of 100Ω, half the differential swing between the output emitters appears at the LMH6555 output terminals as  $V_{\text{OUT}}$ .

#### **[www.ti.com](http://www.ti.com)** SNOSAJ1D –NOVEMBER 2006–REVISED MARCH 2013

With good matching between the input source impedances,  $R_{S1}$  and  $R_{S2}$  shown in [Figure](#page-28-0) 46 and Figure 48, it is possible to infer the gain and output swing by inspection. The differential input impedance of the LMH6555,  $R_{IN\; DIFF}$ , is close to 78Ω.

In differential input drive applications, there is a balanced swing across the input terminals of the LMH6555,  $V_{IN}^+$ and V<sub>IN</sub><sup>-</sup>. So, by using the R<sub>IN\_DIFF</sub> value, one determines the differential current flow through the input terminals and from that the output swing and gain.

$$
V_{IN}^{\dagger} \underbrace{\left\{\begin{array}{c}\text{Rs}_{1} \\ \text{LMH6555} \\ \text{Rs}_{2} \end{array}\right\}}_{P_{S2}} + \underbrace{\left\{\begin{array}{c}\text{R}_{L} \\ \text{LMH6555}\end{array}\right\}}_{P_{L}} \underbrace{\left\{\begin{array}{c}\text{R}_{L} \\ \text{N} \\ \text{100}\Omega\end{array}\right\}}_{VOUT_{+}}
$$

$$
\frac{V_{\text{OUT}}}{V_{\text{IN}}} = \frac{R_F}{2R_S + 78\Omega} = \frac{430\Omega}{2R_S + 78\Omega}
$$
\n(43)

<span id="page-30-0"></span>For the special case where  $R_{S1} = R_{S2} = R_S = 50\Omega$  we have:

for 
$$
R_s = 50\Omega \Rightarrow \frac{V_{OUT}}{V_{IN}} = \frac{430}{178} = 2.42 \text{ V/V}
$$
 (44)

The following is the expression for the Insertion Gain,  $A_V$   $_{\text{DIFF}}$ :

$$
A_{V_DIFF} = \frac{V_{OUT}}{V_{IN} \times \frac{100\Omega}{2R_S + 100}}
$$
  
=  $\frac{V_{OUT}/V_{IN}}{100/200} = 2 V_{OUT}/V_{IN} = 4.83 V/V$   
= 13.7 dB (45)

The expressions above apply equally to the single ended input drive case as well, as long as  $R_{S1} = R_{S2} = 50\Omega$ . For the case of the single ended input drive:

$$
A_{V\_DIFF} = \frac{V_{OUT}}{V_{IN} \times \frac{50}{R_S + 50}}
$$
  
=  $\frac{V_{OUT}/V_{IN}}{50/100} = 2 V_{OUT}/V_{IN} = 4.83 V/V$   
= 13.7 dB (46)

<span id="page-30-1"></span>This is comparable to  $A_V$  DIFF found in Electrical [Characteristics.](#page-2-0)

## **REVISION HISTORY**

www.ti.com 10-Dec-2020

## **PACKAGING INFORMATION**

**(1)** The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

<sup>(2)</sup> RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures. "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (CI) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

**(3)** MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

**(4)** There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

**(5)** Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

**(6)** Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:**The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

## **PACKAGE OPTION ADDENDUM**

# **PACKAGE MATERIALS INFORMATION**

**TEXAS NSTRUMENTS** 

www.ti.com 5-Nov-2021

## **TAPE AND REEL INFORMATION**

## **QUADRANT ASSIGNMENTS FOR PIN 1 ORIENTATION IN TAPE**

www.ti.com 5-Nov-2021

# **PACKAGE MATERIALS INFORMATION**

\*All dimensions are nominal

# **PACKAGE OUTLINE**

# **RGH0016A WQFN - 0.8 mm max height**

PLASTIC QUAD FLATPACK - NO LEAD

NOTES:

- 1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
- 2. This drawing is subject to change without notice.
- 3. The package thermal pad must be soldered to the printed circuit board for optimal thermal and mechanical performance.

# **EXAMPLE BOARD LAYOUT**

## **RGH0016A WQFN - 0.8 mm max height**

PLASTIC QUAD FLATPACK - NO LEAD

4. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature number SLUA271 (www.ti.com/lit/slua271).

5. Vias are optional depending on application, refer to device data sheet. If any vias are implemented, refer to their locations shown on this view. It is recommended that vias under paste be filled, plugged or tented.

# **EXAMPLE STENCIL DESIGN**

# **RGH0016A WQFN - 0.8 mm max height**

PLASTIC QUAD FLATPACK - NO LEAD

NOTES: (continued)

6. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.

## **IMPORTANT NOTICE AND DISCLAIMER**

TI PROVIDES TECHNICAL AND RELIABILITY DATA (INCLUDING DATA SHEETS), DESIGN RESOURCES (INCLUDING REFERENCE DESIGNS), APPLICATION OR OTHER DESIGN ADVICE, WEB TOOLS, SAFETY INFORMATION, AND OTHER RESOURCES "AS IS" AND WITH ALL FAULTS, AND DISCLAIMS ALL WARRANTIES, EXPRESS AND IMPLIED, INCLUDING WITHOUT LIMITATION ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT OF THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

These resources are intended for skilled developers designing with TI products. You are solely responsible for (1) selecting the appropriate TI products for your application, (2) designing, validating and testing your application, and (3) ensuring your application meets applicable standards, and any other safety, security, regulatory or other requirements.

These resources are subject to change without notice. TI grants you permission to use these resources only for development of an application that uses the TI products described in the resource. Other reproduction and display of these resources is prohibited. No license is granted to any other TI intellectual property right or to any third party intellectual property right. TI disclaims responsibility for, and you will fully indemnify TI and its representatives against, any claims, damages, costs, losses, and liabilities arising out of your use of these resources.

TI's products are provided subject to [TI's Terms of Sale](https://www.ti.com/legal/termsofsale.html) or other applicable terms available either on [ti.com](https://www.ti.com) or provided in conjunction with such TI products. TI's provision of these resources does not expand or otherwise alter TI's applicable warranties or warranty disclaimers for TI products.

TI objects to and rejects any additional or different terms you may have proposed.
