

LM8502 Intelligent Lighting Management Unit That Fuses a 1.2A Dual High-Side Flash LED Driver with a 10-Output Low-Side LED Driver

Check for Samples: [LM8502](#)

FEATURES

- 10 Programmable Low-Side Current Sinks with Flexible Powering from V_{OUT} or External Voltage Source
- 1.2A Dual Flash LED Driver with Flash, Torch and Voltage modes
- Ambient Light Sensing Capability with Two Inputs
- Up to 4000:1 dimming ratio for LED outputs
- Flash LED Thermal Sensing and Current Scaleback
- Hardware Flash, Torch Enable and Dual Synchronization Inputs for RF Power Amplifier Pulse Events
- Haptic Feedback Motor Driver
- Two Lighting Engines for User-Defined Lighting Sequences with 48 * 16 Bits of SRAM Memory
- External Clock Pin for Power Save
- External PWM Control Capability Enabling for Example Dynamic Backlight Control
- Fast I²C-Compatible Interface
- General Purpose ADC for Measuring, i.e., LED Output Voltages
- Ultra-Small Solution Area < 32 mm²
- 30-Bump (2.42 x 2.77 mm x 0.6 mm) 0.4 Pitch DSBGA Package

APPLICATIONS

- Camera Phone LED Flash
- General Illumination in Portable Devices
- Haptic Feedback Motor Driver
- Fun Lighting

DESCRIPTION

The LM8502 is a versatile LED driver suitable for multiple applications. It includes a 2MHz, fixed-frequency synchronous boost converter, 10 current sink LED outputs, 2 outputs for flash or haptic applications, ambient light sensing and PWM input.

The 10 current sink LED outputs offer individual current control through an I²C-compatible interface. Current can be accurately controlled with a full-scale setting and 8-bit current control. The LM8502 also enables LED control with group faders and lighting engines. Group faders enable single I²C register writes for multiple LED outputs with fading, whereas lighting engines with SRAM memory enable engine-driven lighting sequences. Each LED output can be powered either from V_{OUT} or an external voltage supply.

The flash function is capable of driving 2 LEDs, each having 600 mA maximum current, or a single LED up to a 1.2A maximum current. A hardware flash enable provides a direct interface to trigger the flash pulse. Dual TX inputs allow the flash to be synchronized with the RF power system to prevent excessive current draw from the system power supply. The LM8502 also offers LED thermal sensing as a safety procedure for flash and separate indicator LED.

The LM8502 has two inputs for Ambient Light Sensing — together with the PWM input they enable Dynamic Backlight Control. The LM8502 may also be used for haptic motor driving instead of flash. When the device is idle, featured Power-save mode and use of an external clock reduce current consumption significantly.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

Pin Descriptions

Name	Pin No.	Description
FLASH2/VIBRAN	A1	High Side Current Source Output for Flash LED or Output for Haptic Feedback
FLASH1/VIBRAP	A2	High Side Current Source Output for Flash LED or Output for Haptic Feedback
OUT	A3, B3	Step-Up DC/DC Converter Output
SW	A4, B4	Drain Connection for Internal NMOS and Synchronous PMOS Switches
GND	A5, B5	Ground
D9	B1	LED Output 9
D10/ALS2	B2	LED Output 10 or Secondary Ambient Light Sensor Input
D7	C1	LED Output 7
D8	C2	LED Output 8
LEDI/NTC	C3	Configurable as a High Side Current Source Output for Indicator LED or Threshold Detector for LED Temperature Sensing (Leave unconnected if not used)
STROBE	C4	Active High Hardware Flash Enable. Drive STROBE high to turn on Flash pulse (Connect to GND if not used)
VIN	C5	Input Voltage Connection
D5	D1	LED Output 5
D6	D2	LED Output 6
ALS1	D3	Primary Ambient Light Sensor Input (Leave unconnected if not used)
PWM/ENVM/TX2	D4	Configurable as PWM Input, an Active High Voltage mode Enable or Dual Polarity Power Amplifier Synchronization Input (connect to GND if not used).
TX1/TORCH	D5	Configurable as an RF Power Amplifier Synchronization Control Input or Hardware Torch Enable (connect to GND if not used).
D3	E1	LED Output 3
D4	E2	LED Output 4
INT	E3	Interrupt for MCU (Leave unconnected if not used)
CLK	E4	External 32 kHz Clock Input (Connect to GND if not used)
EN	E5	Enable/Reset
D1	F1	LED Output 1
D2	F2	LED Output 2
TRIG	F3	Trigger Input/Output for Lighting Engines (Connect to GND if not used)
SCL	F4	Serial Clock Input
SDA	F5	Serial Data Input/Output

BLOCK DIAGRAM

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

Absolute Maximum Ratings ^{(1) (2)(3)}

V_{IN} , V_{SW} , V_{OUT} , $V_{FLASH\ LEDs\ 1,2}$, $V_{LED\ OUTPUTS}$, $V_{LEDI/NTC}$ ⁽⁴⁾	-0.3V to 6V
Voltage on Logic Pins (Input or Output Pins)	-0.3V to $V_{IN}+0.3V$ with 6.0V max
Continuous Power Dissipation ⁽⁵⁾	Internally Limited
Junction Temperature (T_{J-MAX})	+150°C
Storage Temperature Range	-65°C to +150° C
Maximum Lead Temperature (Soldering) ⁽⁶⁾	

- (1) Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings are conditions under which operation of the device is guaranteed. Operating Ratings do not imply guaranteed performance limits. For guaranteed performance limits and associated test conditions, see the Electrical Characteristics table.
- (2) All voltages are with respect to the potential at the GND pin.
- (3) **If Military/Aerospace specified devices are required, please contact the Texas Instruments Sales Office / Distributors for availability and specifications.**
- (4) Voltage spikes on SW pin can be higher than 6V.
- (5) In applications where high power dissipation and/or poor package thermal resistance is present, the maximum ambient temperature may have to be derated. Maximum ambient temperature (T_{A-MAX}) is dependent on the maximum operating junction temperature ($T_{J-MAX-OP} = +125^{\circ}C$), the maximum power dissipation of the device in the application (P_{D-MAX}), and the junction-to-ambient thermal resistance of the part/package in the application (θ_{JA}), as given by the following equation: $T_{A-MAX} = T_{J-MAX-OP} - (\theta_{JA} \times P_{D-MAX})$.
- (6) For detailed soldering specifications and information, please refer to Texas Instruments Application Note 1112: Micro SMD Wafer Level Chip Scale Package (AN-1112).

Operating Ratings

V_{IN}	2.7V to 5.5V
Junction Temperature (T_J) ⁽¹⁾	-30°C to +125°C
Ambient Temperature (T_A)	-30°C to +85°C

- (1) Internal thermal shutdown circuitry protects the device from permanent damage. Thermal shutdown engages at $T_J = 150^{\circ}C$ (typ.) and disengages at $T_J = 135^{\circ}C$ (typ.).

Thermal Properties

Junction-to-Ambient Thermal Resistance (θ_{JA}) ⁽¹⁾	60°C/W
---	--------

- (1) Junction-to-ambient thermal resistance (θ_{JA}) is taken from a thermal modeling result, performed under the conditions and guidelines set forth in the JEDEC standard JESD51-7. The test board is a 4-layer FR-4 board measuring 102mm x 76mm x 1.6mm with a 2x1 array of thermal vias. The ground plane on the board is 50mm x 50mm. Thickness of copper layers are 36 μ m/18 μ m/18 μ m/36 μ m (1.5oz/1oz/1oz/1.5oz). Ambient temperature in simulation is 22°C, still air. Power dissipation is 1W.

Electrical Characteristics⁽¹⁾

Limits in standard typeface are for $T_A = +25^\circ\text{C}$. Limits in boldface type apply over the full operating ambient temperature range ($-30^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$). Unless otherwise specified, $V_{IN} = 3.6\text{V}$, $V_{EN} = V_{IN}$.

(1) Min and Max limits are guaranteed by design, test, or statistical analysis. Typical (Typ) numbers are not guaranteed, but do represent the most likely norm. Unless otherwise specified, conditions for typical specifications are: $V_{\text{IN}} = 3.6\text{V}$ and $T_A = +25^\circ\text{C}$.

(2) Guaranteed by design. $V_{\text{EN}} = 1.65\text{V}$ to V_{IN} .

Electrical Characteristics⁽¹⁾ (continued)

Limits in standard typeface are for $T_A = +25^\circ\text{C}$. Limits in boldface type apply over the full operating ambient temperature range ($-30^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$). Unless otherwise specified, $V_{IN} = 3.6\text{V}$, $V_{EN} = V_{IN}$.

Parameter	Test Conditions	Min	Typ	Max	Units
LED DRIVER ELECTRICAL CHARACTERISTICS					
$I_{LEAKAGE}$	Leakage Current	Outputs D1 to D10	0.1	1	μA
I_{MAX}	Maximum Sink Current	Outputs D1 to D10 (with maximum full-scale current setting)	25.5		mA
I_{OUT}	Output Current Accuracy ⁽³⁾	Output Current Set to 17.5 mA	-5	+5	%
I_{MATCH}	Matching ⁽³⁾	Output Current Set to 17.5 mA	1		
V_{SAT}	Saturation Voltage	Output Current Set to 17.5 mA	45	65	mV
GENERAL PURPOSE ADC ELECTRICAL CHARACTERISTICS					
LSB	Least Significant Bit ⁽⁴⁾		30		mV
E_{ABS}	Total Unadjusted Error ⁽⁵⁾	$V_{IN_TEST} = 0\text{V to } V_{IN}$	± 3		LSB
t_{CONV}	Conversion Time ⁽⁴⁾		2.7		ms
V_{IN_TEST}	DC Voltage Range ⁽⁴⁾		0	5	V
LOGIC INPUT EN VOLTAGE SPECIFICATIONS ($V_{EN} = 1.65$ to V_{IN} unless otherwise noted)					
V_{IL}	Input Logic Low			0.5	V
V_{IH}	Input Logic High	1.2			
I_I	Input Current	-1.0		1.0	μA
LOGIC INPUT SCL, SDA, CLK, STROBE, TX1/TORCH, PWM/ENVM/TX2, TRIG					
V_{IL}	Input Logic Low			$0.2 \times V_{EN}$	V
V_{IH}	Input Logic High	$0.8 \times V_{EN}$			V
I_I	Input Current	-1.0		1.0	μA
LOGIC OUTPUT SDA, TRIG, INT					
V_{OL}	Output Low Level	$I_{OUT} = 3\text{ mA}$		0.3	V
I_L	Output Leakage Current			1.0	μA
RECOMMENDED EXTERNAL CLOCK SOURCE (CLK) CONDITIONS ⁽⁴⁾ ⁽⁶⁾					
f_{CLK}	Clock Frequency		32.7		kHz
t_{CLKH}	High Time		6		μs
t_{CLKL}	Low Time		6		
t_r	Clock Rise Time	10% to 90%		2	
t_f	Clock Fall Time	90% to 10%		2	

- (3) Output Current Accuracy is the difference between the actual value of the output current and programmed value of this current. Matching is the maximum difference from the average. For the constant current outputs on the part (D1 to D10), the following are determined: the maximum output current (MAX), the minimum current (MIN) and the average output current of all outputs (AVG). Two matching numbers are calculated: $(MAX-AVG)/AVG$ and $(AVG-MIN)/AVG$. The largest number of the two (worst case) is considered the matching figure. The typical specification provided is the most likely norm of the matching figure for all parts. Note that some manufacturers have different specifications in use.
- (4) Guaranteed by design. $V_{EN} = 1.65\text{V to } V_{IN}$.
- (5) Total unadjusted error includes offset, full-scale and linearity errors.
- (6) The ideal external clock signal for the LM8502 is a 0V to V_{EN} , 25% to 75% duty-cycle square wave. At frequencies above 32.7 kHz program execution will be faster, and at frequencies below 32.7 kHz program execution will be slower.

Electrical Characteristics⁽¹⁾ (continued)

Limits in standard typeface are for $T_A = +25^\circ\text{C}$. Limits in boldface type apply over the full operating ambient temperature range ($-30^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$). Unless otherwise specified, $V_{IN} = 3.6\text{V}$, $V_{EN} = V_{IN}$.

FUNCTIONAL DESCRIPTION

OVERVIEW

The LM8502 is a 12-LED output driver with a 1.2A synchronous boost converter. Two of the LED outputs are for driving flash LEDs or a haptic vibra motor; 10 current sinks are for general illumination. The device incorporates a 2MHz constant frequency, synchronous, current-mode PWM boost converter.

Pins related to Boost Converter:

- Drain connection for internal NMOS and synchronous PMOS switches, SW pins (A4 and B4)
- Converter Output, OUT pins (A3 and B3)

Pins related to Flash:

- High-side current outputs for Flash LEDs, FLASH1 and FLASH2(A1 and A2), each capable of sourcing up to 600 mA current. If not used for flash, can be used to drive, for example, a vibra motor.
- Active high hardware flash enable STROBE (C4). When set to high turns on the flash pulse. Connect to ground if not used.
- Configurable pin PWM/ENVM/TX2 (D4) can be configured as an active high-voltage-mode enable (ENVM) or as a dual-polarity power-amplifier synchronization input (TX2). Polarity of TX input can be changed with a register bit, and when it occurs, it forces Flash into Torch or Flash LED shutdown. Third function for this pin is PWM input enabling Dynamic Backlight Control. When PWM input is used, ENVM or TX2 cannot be used. Connect to ground if not used.
- Configurable pin TX1/TORCH (D5) can be configured as an RF power amplifier synchronization input of hardware torch enable. At TX1 event the Flash LEDs are forced to Torch mode. In Torch mode, when pin is set high, Flash LEDs are set to Torch current level. Connect to ground if not used.
- Configurable pin LEDI/NTC (C3) can be configured as a high-side current source for indicator LED or threshold detector for flash LED temperature sensing. Indicator LED has four current levels and can be used, for example, as flash event indicator. When configured as NTC, the thermistor senses temperature near flash LEDs; when event occurs, according to a bit setting, flash LEDs are set to either to Torch mode or to shutdown.

Pins related to LED controlling

- LED output pins D1 to D9 (F1 = Output 1, F2 = Output 2, E1 = Output 3, E2 = Output 4, D1 = Output 5, D2 = Output 6, C1 = Output 7, C2 = Output 8 and B1 = Output 9). The current of these current sinks can be programmed through the registers with full-scale current setting and current level. They also can be freely grouped into one of three group faders and be controlled with a single register write. Also incorporated lighting engines can control these current sinks.
- LED output pin D10/ALS2 (B2 = Output 10) is basically same kind of current sink as all others with one exception: it can also be configured as Ambient Light Sensing input.
- Note that all LED outputs can each be freely powered either from V_{OUT} (Converter Output) or external voltage supply.
- TRIG pin (F3) is related to lighting engines. It is used as an external trigger to and from lighting engines.

Other pins

- VIBRAP and VIBRAN pins (A1 and A2) are optional with Flash outputs. They can be used for controlling, for example, a vibra motor from a register or from lighting engines. When not used in haptic applications, they can be used for Flash applications.
- VIN (C5) is the input voltage pin for the device. Voltage range is from 2.7 V to 5.5V.
- ALS1 (D3) is primary Ambient Light Sensing input.
- INT (E3) is interrupt for the micro-controller. Interrupts can come from lighting engine,s as well as from NTC and from ALS zone change.
- CLK (E4) is an external 32 kHz clock input which enables powerful Power-save mode when device is in idle state.
- EN (E5) is the enable or reset pin for the device.
- SCL (F4) and SDA (F5) are the I²C-compatible interface clock input and data input/output.
- GND pins (A5 and B5) are for grounding the device.

MODES OF OPERATION

RESET: In the Reset mode all the internal registers are reset to the default values, and the device goes to Standby mode after reset. CHIP_EN control bit is low after reset by default. Reset mode is entered always if the Reset register is written or internal Power-On Reset is active. the LM8502 can be reset by writing any data to the Reset register (address 3DH). Power-On Reset (POR) will activate during the device startup or when the supply voltage V_{IN} falls below 1.5V. Once V_{IN} rises above 1.5V, POR will inactivate, and the device will continue to the Standby mode.

STANDBY: The Standby mode is entered if POR is inactive. In this mode all circuit functions are disabled. Most of the registers can be written in this mode, and the control bits are effective immediately after startup.

STARTUP: When EN pin is set to '1' the LM8502 initializes EPROM and SRAM memories. Setting the CHIP_EN bit to '1' causes the INTERNAL STARTUP SEQUENCE to power up all the needed internal blocks. If the device temperature rises too high, the Thermal Shutdown (TSD) disables the device operation, and Startup mode is entered until no thermal shutdown is present.

BOOST STARTUP: Soft start for boost is generated in the Boost Startup mode. Boost Startup is entered from INTERNAL STARTUP SEQUENCE if the EN_BOOST bit is set to '1', or from Normal mode when the EN_BOOST bit is set to '1'. During Boost Startup all LED outputs are off to ensure smooth startup.

NORMAL: During Normal mode the user controls the device using the Control registers. The registers can be written in any sequence, and any number of bits can be altered in a register with one write.

POWER-SAVE: Power-save mode is entered when the POWERSAVE_EN bit in Register 36H is set to '1'. This enables a mode where almost all analog blocks are shut down, when the device is idle.

Figure 16. Startup Sequence

LED DRIVER

Overview

The LM8502 has 10 current-sink-type LED outputs. The LED outputs can be controlled in three ways described later on. Each LED output can be powered either from V_{OUT} or from an external voltage supply. The selection of LED output powering can be done from LED control registers (06H to 0FH) with the LEDx_BAT_CON bit. When the LEDx_BAT_CON bit is set to '0', LED output is powered from V_{OUT} . Note that changing LED powering does not enable boost converter automatically. Please also Note that LED output 10 can be configured as an Ambient Light Sensing (ALS) input; the LED output will not turn on when configured as an ALS input.

Table 1. Full-Scale Current

FSC Bit [1:0]	Max LED (mA)	Current step size, linear scale (μ A)
00	3	11.7
01	6	23.5
10	12.5	50
11	25.5	95

Table 2. Current Control When Full-Scale Current Set to 25.5 mA

CURRENT bits	Output Current
0000 0000	0.0 mA
0000 0001	0.1 mA
0000 0010	0.2 mA
....
10101111	17.5 mA
...
11 111 111	25.5 mA

The Brightness Control register (BRGT) is an 8-bit register that programs the 255 different LED current levels. The code written to BRGT is translated into an LED current as a percentage of ILED_FULLSCALE as set via the full-scale current bits (LED control registers bits [4:3]). There are two selectable LED current profiles. Setting LED control register bit 5 to '1' selects the logarithmic LED current response; setting this bit to '0' selects the linear weighted curve. With the maximum full-scale current and logarithmic setting one can achieve up to 4000:1 dimming ratio with maximum full-scale setting at the first steps of logarithmic curve ($6.25 \mu\text{A}/25.5 \text{ mA} = 1/4080$). Current steps are displayed in Table 2 for linear scale. With a logarithmic setting the step size varies, but is at minimum $0.78 \mu\text{A}$ when full-scale control is 00, and $6.25 \mu\text{A}$ when full-scale control is 11.

For LED dimming a logarithmic or linear scale can be applied — see the figure Figure 17. A logarithmic or linear scheme can be set for both the program execution engine control and direct brightness control. By using a logarithmic brightness scale the visual effect looks like linear to the human eye. The logarithmic brightness scale is created with technique, which has internal resolution of 12 bits. (8-bit control can be seen by user.)

Figure 17. LED Dimming In Linear and Logarithmic Modes

Controlling Brightness of LED Outputs

1. Direct Brightness Control

- All LM8502 LED drivers, D1 to D10, can be controlled independently through the two-wire serial I²C-compatible interface. For each high-side driver there is a current control register.

2. Controlling by Program Execution Engines

- Engine control is used when the user wants to create programmed sequences. The program execution engine has higher priority than direct control registers. Therefore, if the user has set a certain value to the current register, it will be automatically overridden when the program execution engine controls the driver. LED control and program execution engine operation are described later on.

3. Group Fader Control

- In addition to LED-by-LED current register control, the LM8502 is equipped with group fader control which allows the user to fade in or fade out multiple LEDs by writing to only one register. This is a useful function to minimize serial bus traffic between the MCU and the LM8502. The LM8502 has three group fader registers, thus, it is possible to form three fader groups. Fade-in and fade-out times can also be set with the device. These times control the time when ramping up or down the group current value. Time can be set with 4 bits according to the following table:

Table 3. Fade in/out times

FADE IN/FADE OUT	Time, s
0000	0.0
0001	0.05
0010	0.1
0011	0.2
0100	0.3
0101	0.4
0110	0.5
0111	0.6
1000	0.7
1001	0.8
1010	0.9
1011	1.0
1100	1.5
1101	2.0
1110	3.0
1111	4.0

- When the LM8502 is shut down (through chip_en), the fading off may be achieved. When the “fade-to-off” bit is set to 1, the group fade times have effect, and the LEDs fade off according to the time set in the register. Note that Ambient Light Sensing and PWM input are also set through these group fader controls.

LM8502 ENGINE PROGRAMMING

The LM8502 has two independent programmable lighting engines. Both lighting engines have their own program memory block allocated by the user. Note that in order to access program memory the operation mode needs to be LOAD Program, at least for one of the lighting engines. Please also note also that one should not change from RUN mode directly to LOAD program. Correct sequence would be RUN (10) → DISABLED (00) → LOAD (01). Program execution is clocked with 32 768 Hz clock. This clock can be generated internally or by using an external 32 kHz clock that can be connected to CLK pin. Use of an external clock enables synchronization of LED timing to this clock rather than to the internal clock. Note that the last instruction in the memory should be END or GO_TO_START.

The engines have different priorities; when more than one engine is controlling the same LED output, LED engine 1 has the higher priority than LED engine 2. Supported instruction set is listed in the tables below:

Table 4. LM8502 LED Driver Instructions

RAMP INSTRUCTIONS

RAMP Instruction

This instruction is useful for smoothly changing from one brightness value into another on the D1 to D10 outputs, in other words generating ramps (with a negative or positive slope). The LM8502 allows programming of very fast and very slow ramps.

Ramp instruction generates a brightness ramp, using the effective brightness value as a starting value. At each ramp step the output is incremented/decremented by one unit, unless the step time span is 0 or incremental value is 0. Time span for one ramp step is defined with prescale-bit [14] and step time-bits [13:9]. Prescale = 0 sets 0.49 ms cycle time, and prescale = 1 sets 15.6 ms cycle time, so the minimum time span for one step is 0.49 ms (prescale * step time span = 0.49ms x 1); the maximum time span is 15.6 ms x 31 = 484ms/step.

If all the step time bits [13:9] are set to zero, depending on the prescale instruction works as absolute or relative set_brightness instruction. If prescale is set to '0' (Set Brightness Relative value), all the mapped LED outputs are increased or decreased (depending on the sign bit) with a value defined by # of increments in 0.49 ms. With relative value the sign defines whether the BRGT value is decremented or incremented. If the prescale is set to '1' (Set Brightness Absolute value), all the mapped LED outputs are set to same current level defined by # of increments in 0.49 ms regardless of the effective brightness level.

The incremental value defines how many steps will be taken during one ramp instruction — increment maximum value is 255d, which equals incrementing from zero value to the maximum value. If brightness reaches minimum/maximum value (0/255) during the ramp instruction, the ramp instruction will be executed to the end regardless of saturation. This enables ramp instruction to be used as a combined ramp & wait instruction. Note: Ramp instruction is the wait instruction when the increment bits [7:0] are set to zero. Setting bit LOG_EN high/low sets logarithmic (1) or linear ramp (0). By using the logarithmic ramp setting the visual effect appears like a linear ramp, because the human eye behaves in a logarithmic way.

Table 11. RAMP

Name	Value (d)	Description
prescale	0	Divides master clock (32.768 Hz) by 16 = 2048 Hz resulting 0.488 ms cycle time
	1	Divides master clock (32.768 Hz) by 512 = 64 Hz resulting 15.625 ms cycle time
sign	0	Increase brightness output
	1	Decrease brightness output
step time	0 - 31	One ramp increment done in (step time) x (prescale).
# of increments	0 - 255	The number of increment/decrement cycles Note: Value 0 takes the same time as increment

FAST RAMP Instruction

The fast ramp instruction generates a brightness ramp, using the effective brightness value as a starting value. At each ramp step the output is incremented/decremented by step size. Time span for one ramp step is always 0.49 ms. The time span for the whole ramp is determined by the number of increments. For example if step size is 4 and the number of increments is 40, the whole ramp time span is $40 \times 0.49 \text{ ms} = 19.6 \text{ ms}$. For every 0.49 ms mapped, output brightnesses are incremented by 4, so full ramp increments the mapped output values by $40 \times 4 = 160$.

Table 12. FAST RAMP

sign	0	Increase brightness output
	1	Decrease brightness output
step size	0–3 (0=2, 1=4, 2=8, 3=16)	Value indicating how much the brightness is incremented in 0.49 ms
# of increments	1–63	The number of increment/decrement cycles

RAMP Instruction with Variables

Programming ramps with variables is very similar to programming ramps with numerical operands. The only difference is that when the instruction is started, the step time and number of increments are captured from variable registers. If the variables are updated after starting the instruction execution, it will have no effect on instruction execution. Again, at each ramp step the mapped outputs are incremented/decremented by one unless step time is 0 or increment is 0. Time span for one step is defined with prescale and step time bits. Step time is defined with variables A, B, C or D. Variables A, B and C are set with LED instruction. Variable D is a global variable and can be set by writing the I²C Variable register 3CH. General purpose ADC result can be used as a source for variable D as well. Note that FAST RAMP instruction cannot use variables.

Table 13. RAMP with Variable

Name	Value (d)	Description
step time	0–3 0 = local variable A 1 = local variable B 2 = global variable C 3 = I ² C variable register value or general purpose ADC value, variable D	One ramp increment done in (step time) x (prescale). Step time is loaded with the value of the variable. The value of the variable should be from 0–31 for correct operation
# of increments	0–3 0 = local variable A 1 = local variable B 2 = global variable C 3 = I ² C variable register value or general purpose ADC value, variable D	The number of increment/decrement cycles. Value is taken from variable.

LED MAPPING INSTRUCTIONS

These commands define the engine-to-LED mapping. The mapping information is stored in a table, which is stored in the SRAM (program memory of the LM8502). Location of the mapping table can exist anywhere in SRAM. LM8502 has two lighting engines (Engines) which can be mapped to 10 LED drivers or haptic driver freely. Each mapping takes one 16-bit instruction and a mapping table consists of multiple mappings. The engines can use the same mapping table or have their own mapping table. Each of the LED outputs or haptic output is mapped by following manner (note that this is also the way they are written into the SRAM memory):

Each mapping takes one 16-bit instruction and a mapping table consists of multiple mappings. The engines can use the same mapping table or have their own mapping table. Each of the LED outputs or haptic output is mapped by following manner (note that this is also the way they are written into the SRAM memory):

Table 14. LED Mapping

Output	Value (dec) / (binary)
LED1	1 / 0000 0000 0000 0001
LED2	2 / 0000 0000 0000 0010
LED3	4 / 0000 0000 0000 0100
LED4	8 / 0000 0000 0000 1000
LED5	16 / 0000 0000 0001 0000
LED6	32 / 0000 0000 0010 0000
LED7	64 / 0000 0000 0100 0000
LED8	128 / 0000 0000 1000 0000
LED9	256 / 0000 0001 0000 0000
LED10	512 / 0000 0010 0000 0000
Haptic	1024 / 0000 0100 0000 0000

One mapping can control one or multiple LED outputs or haptic. In a case where multiple LED outputs or LED outputs and haptic are mapped, one sets to '1' the applicable 'LED/haptic bit'. For example:

Table 15. Mapping Example

Mapped Outputs	Value (dec) / (binary)
LED1, LED3 and LED9	261 / 0000 0001 0000 0101
LED2, LED4, LED6, LED8, LED10 and haptic	1706 / 0000 0110 1010 1010

There are totally seven commands for the engine-to-LED driver control: mux_ld_start, mux_ld_end, mux_sel, mux_clr, mux_inc, mux_dec, mux_set. Note that the LED mapping instructions do not update brightness values to LED outputs. Brightness values are updated after ramp or set_brgt instructions.

MUX_LD_START; MUX_LD_END Instructions

Mux_ld_start and mux_ld_end define the mapping table location in the memory. Mux_ld_start defines the start address, and mux_ld_end indicates the end address of the mapping table.

MUX_SEL Instruction

With a mux_sel instruction one, and only one, LED driver can be connected to a lighting engine. Connecting multiple LEDs to one engine is done with the mapping table. After the mapping has been released from an LED, the brightness register value will still control the LED brightness.

Table 16. MUX_SEL

Name	Value (d)	Description
LED select	0 - 16	0 = no drivers selected 1 = LED1 selected 2 = LED2 selected ... 9 = LED9 selected 10 = LED10 selected 11 = haptic

MUX_CLR Instruction

Mux_clr clears engine-to-driver mapping. After the mapping has been released from an LED, the Brightness register value will still control the LED brightness.

MUX_INC Instruction

Mux_inc instruction sets the next row active in the mapping table each time it is called. For example, if the 2nd row is active after a mux_inc instruction call, the 3rd row will be active. If the mapping table end is reached, activation will roll to the mapping table start address the next time the mux_inc instruction is called. The engine will not push a new brightness value to the LED driver output before a SET_BRGT or RAMP instruction is executed. If the mapping has been released from an LED, the value in the Brightness register will still control the LED brightness.

MUX_DEC Instruction

Mux_dec instruction sets the previous row active in the mapping table each time it is called. For example, if the 3rd row is active, after mux_dec instruction call the 2nd row will be active. If the mapping table start address is reached, activation will roll to the mapping table end address the next time the mux_dec instruction is called. The engine will not push a new brightness value to the LED driver output before a SET_BRGT or RAMP instruction is executed. If the mapping has been released from an LED, the value in the Brightness register will still control the LED brightness.

MUX_SET Instruction

Mux_set sets the index pointer to point to the mapping table row defined by bits [6:0] and sets the row active. The engine will not push a new brightness value to the LED driver output before SET_BRGT or RAMP instruction is executed. If the mapping has been released from an LED, the value in the Brightness register will still control the LED brightness.

SET BRIGHTNESS INSTRUCTIONS

SET BRIGHTNESS Instruction

This instruction is used for setting the brightness value on the outputs D1 to D10 and haptic without any ramps. Set BRGT output value from 0 to 255 with BRGT value bits [7:0]. Instruction execution takes sixteen 32 kHz clock cycles (=488 μ s). Setting the brightness can be relative or absolute depending on bit [14]. If bit is set to '0' (Set Brightness Relative value), all the mapped LED outputs are increased or decreased (depending on the sign bit) with a value defined by the BRGT value in 0.49 ms. With relative value bit [8] defines whether the BRGT value is decremented or incremented. If the prescale is set to '1' (Set Brightness Absolute value), all the mapped LED outputs are set to the same current level defined by the BRGT value in 0.49 ms regardless of the effective brightness level.

Table 17. SET BRIGHTNESS

Name	Value (d)	Description
Setting type	0–1 0 = relative setting 1 = absolute setting	Defines how the brightness of mapped LED or haptic outputs is set
Sign (only for relative setting)	0–1 0 = increase brightness 1 = decrease brightness	Defines whether the brightness value is increased or decreased with the BRGT value
BRGT value	0–255	BRGT output value 0 100%

SET BRIGHTNESS with Variable Instruction

Table 18. SET BRIGHTNESS with Variable

Name	Value (d)	Description
Variable	0–3	0 = local variable A 1 = local variable B 2 = global variable C 3 = I ² C variable register value or general purpose ADC value, variable D

WAIT INSTRUCTION

When a wait instruction is executed, the engine is set in a wait status, and the brightness values on the outputs are frozen.

Table 19. WAIT

Name	Value (d)	Description
prescale	0	Divide master clock (32.768 Hz) by 16 which means 0.488 ms cycle time
	1	Divide master clock (32 768 Hz) by 512 which means 15.625 ms cycle time
time	1– 31	Total wait time will be = (time) x (prescale). Maximum 484 ms, minimum 0.488 ms

LED MAPPING INSTRUCTIONS

These commands define the engine-to-LED mapping. The mapping information is stored in a table, which is stored in the SRAM (program memory of the LM8502). Location of the mapping table can exist anywhere in SRAM. LM8502 has two lighting engines (Engines) which can be mapped to 10 LED drivers or haptic driver freely. Each mapping takes one 16-bit instruction and a mapping table consists of multiple mappings. The engines can use the same mapping table or have their own mapping table. Each of the LED outputs or haptic output is mapped by following manner (note that this is also the way they are written into the SRAM memory):

These commands define the engine-to-LED mapping. The mapping information is stored in a table, which is stored in the SRAM (program memory of the LM8502). Location of the mapping table can exist anywhere in SRAM. LM8502 has two lighting engines (Engines) which can be mapped to 10 LED drivers or haptic driver freely. Each mapping takes one 16-bit instruction and a mapping table consists of multiple mappings. The engines can use the same mapping table or have their own mapping table. Each of the LED outputs or haptic output is mapped by following manner (note that this is also the way they are written into the SRAM memory):

Table 20. LED Mapping

Output	Value (dec) / (binary)
LED1	1 / 0000 0000 0000 0001
LED2	2 / 0000 0000 0000 0010
LED3	4 / 0000 0000 0000 0100
LED4	8 / 0000 0000 0000 1000
LED5	16 / 0000 0000 0001 0000
LED6	32 / 0000 0000 0010 0000
LED7	64 / 0000 0000 0100 0000
LED8	128 / 0000 0000 1000 0000
LED9	256 / 0000 0001 0000 0000
LED10	512 / 0000 0010 0000 0000
Haptic	1024 / 0000 0100 0000 0000

One mapping can control one or multiple LED outputs or haptic. In a case where multiple LED outputs or LED outputs and haptic are mapped, one sets to '1' the applicable 'LED/haptic bit'. For example:

Table 21. Mapping Example

Mapped Outputs	Value (dec) / (binary)
LED1, LED3 and LED9	261 / 0000 0001 0000 0101
LED2, LED4, LED6, LED8, LED10 and haptic	1706 / 0000 0110 1010 1010

There are totally seven commands for the engine-to-LED driver control: `mux_ld_start`, `mux_ld_end`, `mux_sel`, `mux_clr`, `mux_inc`, `mux_dec`, `mux_set`. Note that the LED mapping instructions do not update brightness values to LED outputs. Brightness values are updated after `ramp` or `set_brgt` instructions.

MUX_LD_START; MUX_LD_END Instructions

`Mux_ld_start` and `mux_ld_end` define the mapping table location in the memory. `Mux_ld_start` defines the start address, and `mux_ld_end` indicates the end address of the mapping table.

MUX_SEL Instruction

With a `mux_sel` instruction one, and only one, LED driver can be connected to a lighting engine. Connecting multiple LEDs to one engine is done with the mapping table. After the mapping has been released from an LED, the Brightness register value will still control the LED brightness.

Table 22. MUX_SEL

Name	Value (d)	Description
LED select	0 - 16	0 = no drivers selected 1 = LED1 selected 2 = LED2 selected ... 9 = LED9 selected 10 = LED10 selected 11 = haptic

MUX_CLR Instruction

`Mux_clr` clears engine-to-driver mapping. After the mapping has been released from an LED, the Brightness register value will still control the LED brightness.

MUX_INC Instruction

`Mux_inc` instruction sets the next row active in the mapping table each time it is called. For example, if the 2nd row is active after a `mux_inc` instruction call, the 3rd row will be active. If the mapping table end is reached, activation will roll to the mapping table start address the next time the `mux_inc` instruction is called. The engine will not push a new brightness value to the LED driver output before a `SET_BRGT` or `RAMP` instruction is executed. If the mapping has been released from an LED, the value in the Brightness register will still control the LED brightness.

MUX_DEC Instruction

`Mux_dec` instruction sets the previous row active in the mapping table each time it is called. For example, if the 3rd row is active, after `mux_dec` instruction call the 2nd row will be active. If the mapping table start address is reached, activation will roll to the mapping table end address the next time the `mux_dec` instruction is called. The engine will not push a new brightness value to the LED driver output before a `SET_BRGT` or `RAMP` instruction is executed. If the mapping has been released from an LED, the value in the Brightness register will still control the LED brightness.

MUX_SET Instruction

`Mux_set` sets the index pointer to point to the mapping table row defined by bits [6:0] and sets the row active. The engine will not push a new brightness value to the LED driver output before `SET_BRGT` or `RAMP` instruction is executed. If the mapping has been released from an LED, the value in the Brightness register will still control the LED brightness.

GO-TO-START INSTRUCTION

Go-to-start command resets the Program Counter register; the program continues executing from the I²C register program start address. Command takes sixteen 32 kHz clock cycles. Note that default value for all program memory registers is 00h, which is the “Go-to-Start” command.

BRANCH

BRANCH Instruction

Branch instruction is mainly indented for repeating a portion of the program code several times. Branch instruction loads step number value to program counter. The loop-count parameter defines how many times the instructions inside the loop are repeated. The LM8502 supports nested looping, i.e., loop inside loop. The number of nested loops is not limited. Instruction takes sixteen 32 kHz clock cycles.

Table 23. BRANCH Instruction

Name	Value (d)	Description
loop count	0-63	The number of loops to be done. 0 means an infinite loop.
step number	0-95	The step number to be loaded to program counter

BRANCH Instruction with Variable

Table 24. BRANCH Instruction with Variable

Name	Value (d)	Description
step number	0-3 0 = local variable A 1 = local variable B 2 = global variable C 3 = I ² C variable register value or general purpose ADC value, variable D	Selects the variable for step number value. Step number is loaded with the value of the variable.

INT INSTRUCTION

Sends interrupt to processor by pulling the INT pin down and setting the corresponding status bit high. Interrupt can be cleared by reading interrupt bits in STATUS/INTERRUPT register. With this instruction program execution continues.

END INSTRUCTION

Ends program execution and resets PC. Instruction takes sixteen 32 kHz clock cycles. End instruction can have two parameters, INT and RESET. These parameters are described in tables below. Execution engine bits are set to zero, i.e., Hold mode.

Table 25. END Instruction

Name	Value	Description
int	0	No interrupt will be sent. PWM registers values will remain intact. Program counter value is set to 0.
	1	Reset program counter value to 0 and send interrupt to processor by pulling the INT pin down and setting corresponding status bit high to notify that program has ended. Brightness register values will remain intact. Interrupt can be cleared by reading interrupt bits in STATUS/INTERRUPT register

Table 25. END Instruction (continued)

Name	Value	Description
reset	0	Reset program counter value to 0 and hold. Brightness register values remain intact.
	1	Reset program counter value to 0 and hold. Brightness register values of the non-mapped drivers will remain. Brightness register values of the mapped drivers will be set to '0000 0000'.

TRIGGER INSTRUCTION

Wait or send triggers can be used to, e.g., synchronize operation between the program execution engines. A send trigger instruction takes sixteen 32 kHz clock cycles, and a wait for trigger takes at least sixteen 32 kHz clock cycles. The receiving engine stores the triggers which have been sent. Received triggers are cleared by a wait-for-trigger instruction. A wait-for-trigger instruction is executed until all the defined triggers have been received. (Note: several triggers can be defined in the same instruction.) An external trigger input signal must stay low for at least two 32 kHz clock cycles to be executed. Trigger output signal is three 32 kHz clock cycles long. External trigger signal is active low, i.e. when trigger is send/received the pin is pulled to GND. Sent external trigger is masked, i.e., the device which has sent the trigger will not recognize it. If send and wait external triggers are used on the same instruction, the send external trigger is executed first, then the wait external trigger.

Table 26. TRIGGER Instruction

Name	Value (d)	Description
wait for a trigger	0 - 31	Wait for a trigger from the engine (s). Several triggers can be defined in the same instruction. Bit [7] engages engine 1, bit [8] engages engine 2, and bit [6] is for external trigger I/O. Bits [4], [5] and [9] are not in use.
send a trigger	0 - 31	Send a trigger to the engine(s). Several triggers can be defined in the same instruction. Bit [1] engages engine 1, bit [2] engages engine 2, and bit [6] is for external trigger I/O. Bits [3], [4] and [5] are not in use.

CONDITIONAL INSTRUCTIONS

The LM8502 includes the following conditional jump instructions: jne (jump if not equal), jge (jump if greater or equal), jl (jump if less) and je (jump if equal). If the condition is true, a certain number of instructions will be skipped (i.e., the program jumps forward to a location relative to the present location). If condition is false, then the next instruction will be executed.

Table 27. Conditional Instruction

Name	Value (d)	Description
Number of instructions to be skipped if the operation returns true	0–31	The number of instructions to be skipped when statement is true. Note: value 0 means redundant code
variable 1	0–3	0 = local variable A 1 = local variable B 2 = global variable C 3 = I ² C variable register value or general purpose ADC value, variable D
variable 2	0–3	0 = local variable A 1 = local variable B 2 = global variable C 3 = I ² C variable register value or general purpose ADC value, variable D

ARITHMETIC INSTRUCTIONS

LD

This instruction is used to assign a value into a variable; the previous value in that variable is overwritten. Both engines have two local variables called A and B. The variable C is a global variable for both engines.

Table 28. Assign Value to Variable

Name	Value (d)	Description
target variable	0–2	0 = variable A 1 = variable B 2 = variable C
8-bit value	0–255	Variable value

ADD

Operator either adds 8-bit value to the current value of the target variable, or adds the value of variable 1 (A, B, C or D) to the value of variable 2 (A, B, C or D) and stores the result in the register of variable A, B or C. Variables overflow from 255 to 0.

Table 29. ADD with Numerical Operands

Name	Value (d)	Description
target value	0–2	0 = variable A 1 = variable B 2 = variable C
8-bit value	0–255	The value to be added

Table 30. ADD with Variables

Name	Value (d)	Description
target value	0–2	0 = variable A 1 = variable B 2 = variable C
variable 1	0–3	0 = local variable A 1 = local variable B 2 = global variable C 3 = I ² C variable register value or general purpose ADC value, variable D
variable 2	0–3	0 = local variable A 1 = local variable B 2 = global variable C 3 = I ² C variable register value or general purpose ADC value, variable D

SUB

Operator either subtracts 8-bit value to the current value of the target variable, or subtracts the value of variable 1 (A, B, C or D) to the value of variable 2 (A, B, C or D) and stores the result in the register of variable A, B or C. Variables overflow from 255 to 0.

Table 31. SUB with Numerical Operands

Name	Value (d)	Description
target value	0–2	0 = variable A 1 = variable B 2 = variable C
8-bit value	0–255	The value to be subtracted

Table 32. SUB with variables

Name	Value (d)	Description
target value	0–2	0 = variable A 1 = variable B 2 = variable C
variable 1	0–3	0 = local variable A 1 = local variable B 2 = global variable C 3 = I ² C variable register value or general purpose ADC value, variable D
variable 2	0–3	0 = local variable A 1 = local variable B 2 = global variable C 3 = I ² C variable register value or general purpose ADC value, variable D

HAPTIC FEEDBACK

The LM8502 can be set to Haptic Feedback mode, where the FLASH1/VIBRAP and FLASH2/VIBRAN pins can be used for driving a vibra motor. The device incorporates H-bridge which is controlled with a PWM generator. The PWM generator can be controlled through writing I²C registers or lighting engines or through grouping haptic into one of the group faders. PWM frequency can be selected with 2 bits (bits [4:3] in the Haptic Feedback Control register 21H) in the following manner: 00 = 157 Hz, 01 = 490 Hz, 10 = 980 Hz, 11 = 3.9 kHz. PWM has 8-bit resolution. Different haptic modes can be selected according to [Table 34](#).

These different modes control the direction of vibra motor. The PWM control sets the speed of the motor. See [Figure 18](#) and [Table 33](#) below.

- In mode 000 the haptic is disabled.
- In mode 001 there is PWM on both A and B channels. The frequency of the PWM is double the frequency set in register 21H Haptic control 2. When the PWM value is 00H the B-channel is fully on, the A-channel is off, and the motor is running clockwise. Increasing the PWM value increases the A-channel pulse length and decreases B-channel pulse length. In the middle of the PWM range (value 80H) both channels PWM have the same pulse length so that the motor is stopped. When the PWM reaches value FFH, the A channel is fully on, the B channel is off and motor is running counterclockwise.
- In mode 010 the PWM register controls the A-channel; B-channel is in low state (off) all the time. Increasing the PWM increases the motor speed. The motor is running counter clockwise.
- In mode 011 the PWM register controls the B-channel; A-channel is in low state (off) all the time. Increasing the PWM increases the motor speed. The motor is running clockwise.
- In mode 100 the haptic is disabled.
- In mode 101 the PWM is on both channels. The functionality is the same as in mode 001 with one exception. In the middle PWM value (80H) there is no activity on either of the channels. This is to save power in the middle value.
- In mode 110 the PWM register controls the A-channel; B-channel is in high state (on) all the time. With PWM value 00H the motor is running at full speed. Increasing the PWM value reduces the motor speed. Motor is running clockwise.
- In mode 111 the PWM register controls the B-channel; A-channel is in high state (on) all the time. With PWM value 00H the motor is running at full speed. Increasing the PWM reduces the motor speed. Motor is running counter-clockwise.

Figure 18.

Table 33. H-Bridge Truth Table

PFET Left A-channel	NFET Left A-channel	PFET Right B-channel	N-fet Right B-channel	Operation of the motor
On	Off	Off	On	Motor goes Clockwise
Off	On	On	Off	Motor goes Counter-Clockwise
On	Off	On	Off	Motor 'brakes'
Off	On	Off	On	Motor 'brakes'

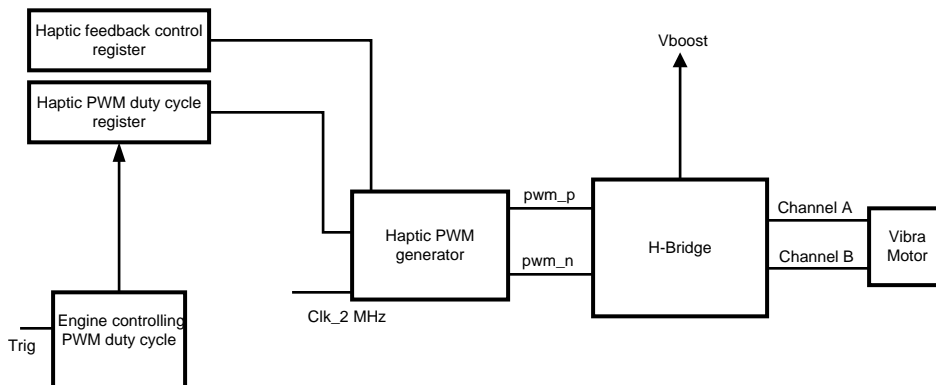

Table 34. Haptic Modes

HAPT_SEL_MODE[2:0]	Description
000	Haptic disabled
001	PWM to both channels ($2 \times \text{pwm_freq}$)
010	PWM on A channel, B channel in low state
011	PWM on B channel, A channel in low state
100	Haptic disabled
101	PWM to both channels, no activity at center value ($2 \times \text{pwm_freq}$)
110	PWM on A channel, B channel in high state
111	PWM on B channel, A channel in high state

Haptic can be controlled with the lighting engines also. Haptic is mapped to the engines like LED outputs with mapping tables of with mux_sel instruction. All the instructions work the same with haptic as with the LED outputs. One must take into account which haptic mode is selected, since the haptic mode cannot be changed with the engines, but only from registers with I²C.

Haptic can be used also instead of the PWM input. This enables, for example, the use of lighting engines with ALS or PWM control directly from register. Haptic is selected instead of PWM input by setting bit [1] in register 36H PWM_INPUT_SEL to '0'. When in Haptic mode there is a one-second wait before going to Power-save mode. This allows the vibra motor to stop without causing any issues to the LM8502.

During haptic operation boost is set to Constant Voltage mode (selectable 4.5V or 5.0V).

AMBIENT LIGHT SENSING

The LM8502 incorporates an Ambient Light Sensing (ALS) input interface which translates an analog output of ambient light sensor, to a user specified brightness level. In LM8502 there are two ALS inputs. One is dedicated solely to ambient light sensing (ALS1), the other is multiplexed with LED output 10 (ALS2). Note that when ALS2 is in use LED output D10 cannot be enabled. If the two ALS inputs are selected, the ALS input functionality can be defined with two bits in ALS Control register 11H as described in Table 35.

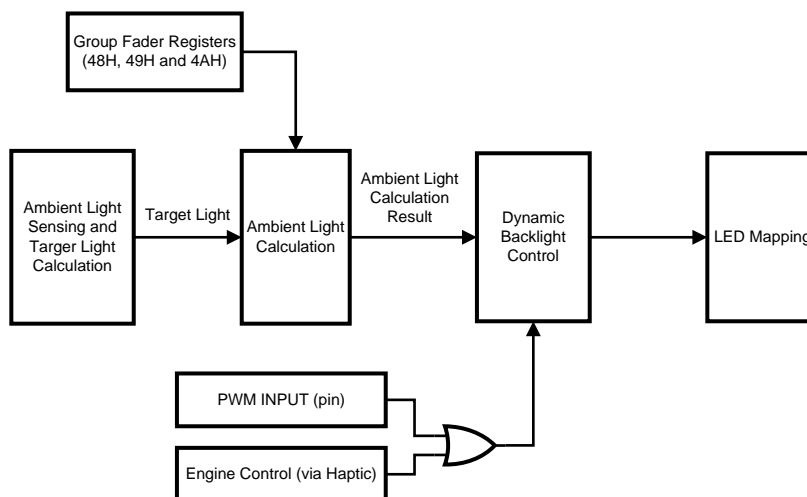

Figure 19. Ambient Light Sensing

Table 35. Ambient Light Sensor Input Functionality

ALS_SEL[1:0]	Function
00	The lowest of ALS1 or ALS2 is the ambient light sensor input
01	ALS1 is the ambient light sensor input
10	ALS2 is the ambient light sensor input
11	The highest of ALS1 or ALS2 is the ambient light sensor input

ALS is designed so that it controls the LED outputs through the group controls. LED outputs, which should be controlled by the ambient light sensing, need to be grouped into one of the three groups. There is an enable for each group that selects whether the ALS affects a certain group or not. For example, one group of LED outputs may be controlled by ALS along, another by ALS and PWM, and the third group may be controlled only from the Group Fader register (ALS or PWM having no effect on this group).

Each group fader register value scales the ALS input. This enables different brightness levels for different groups. After ALS input is multiplied with group scaling it is multiplied with PWM control (if the PWM is selected for the group). The control for PWM can come from the external PWM input pin or from the lighting engines. When PWM control comes from the lighting engines, the Haptic outputs cannot be used. After ALS input is multiplied with PWM control it is mapped into LED outputs. (See the ALS sensing flow in [Figure 22](#).) The Ramp control manages LED current-level transitions from one desired brightness code to the next, as described in the section regarding Group Fader Control.

Table 36. Ambient Light Truth Table: How ALS and PWM Enables Affect Group of LED Outputs

Grouping	ALS_en	PWM_en	Current value mapped to LED outputs
no	works only when LED outputs grouped	works only when LED outputs grouped	LED outputs controlled through register or lighting engine
yes	no	no	Group current control
yes	yes	no	Group current x ALS
yes	no	yes	Group current x PWM
yes	yes	yes	Group current x ALS x PWM

ALS is controlled with the ALS_en_G1, ALS_en_G2 and ALS_en_G3 bits. Setting one of these bits to '1' turns on the ALS circuitry.

The LM8502 incorporates internal resistors for scaling ambient light sensor currents. This enables the use of different sensors and also the high impedance state when device is in standby, which saves energy. Note that the internal resistor value is the same for both of the ambient light inputs, which means that when using both ALS inputs sensors must be the same. Use of an external resistor is also possible. When an external resistor is used the en_ext_res bit should be set to '1'. When en_ext_res is set to '0', the internal resistor is selected with the als_res_sel[1:0] bits. see [Table 37](#).

Table 37. Ambient Light Resistor Selection

EN_EXT_RES	ALS_RES_SEL[1:0]	Resistor value (kOhm)
0	00	1.25
0	01	2.5
0	10	5
0	11	10
1	X (don't care)	external resistor

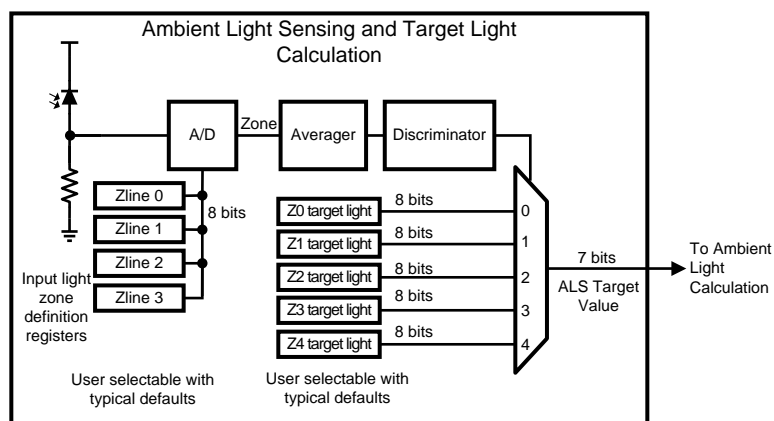

Figure 20. Ambient Light Sensing and Target Light Calculation

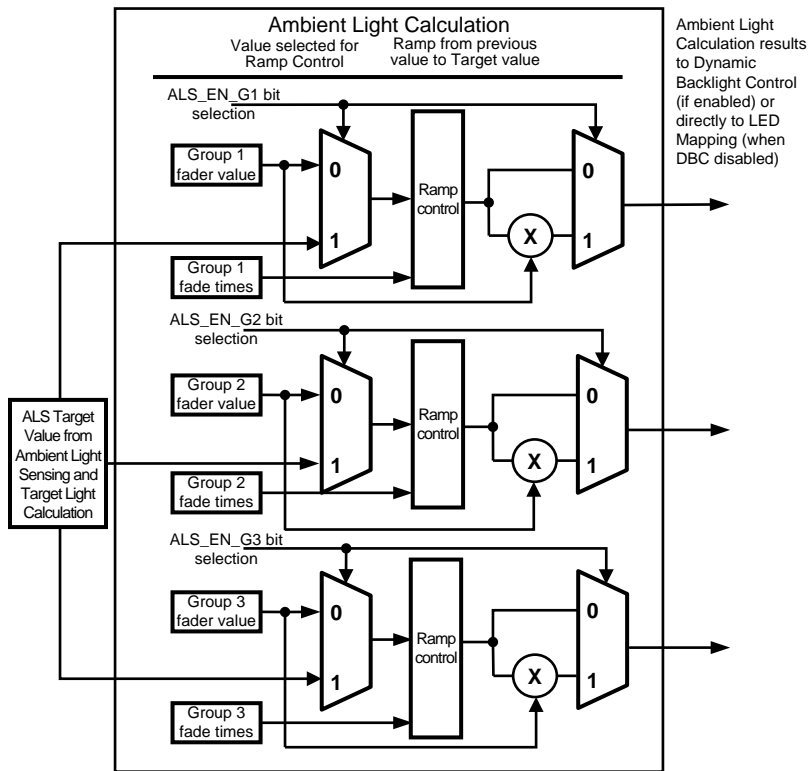

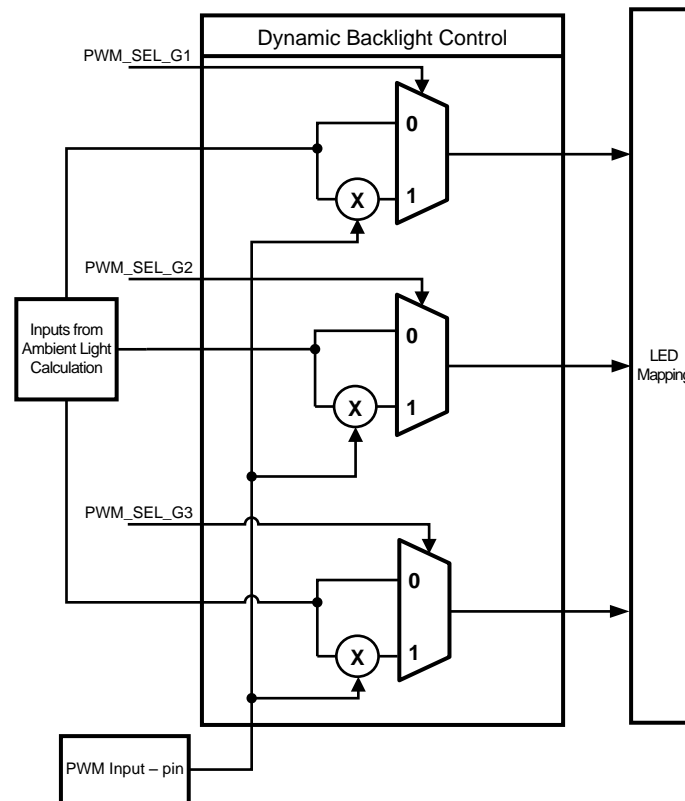

Figure 21. Ambient Light Calculation

Dynamic Backlight Control

Figure 22. Ambient Light Sensing Functionality

The ALS circuit has four programmable thresholds which define five ambient brightness zones. The Zline0 – Zline3 and Z0 Target Light – Z4 Target Light registers control the user-selectable thresholds and brightness levels for the different zones. It is also possible to set the start value from which the ALS starts when enabled. ALS start zone can be selected with 3 bits in ALS_START_VALUE control register 1BH, as shown in Table 38 to following table. ALS start zone will be taken after startup or after power-save. ALS zone data is readable from register 97H.

When ALS has changed from zone to another, the ALS_ZONE_CHANGE bit in the STATUS/INTERRUPT register (3AH) is set to '1'. Reading this register clears the bit. When an interrupt is wanted from ALS zone, the MASK_ALS_ZONE_INT bit in MISC register (36H), must be set to '0'. This bit is '1' by default. When this bit is set to '0' ALS gives interrupt when zone changes, and INT output will go to into a low state. Read-back of the Status/Interrupt register will cause the INT output to go to a high state.

Table 38. ALS Start Zone Selection

zone_start[2:0]	ALS start value
000	Zone 0 target value
001	Zone 1 target value
010	Zone 2 target value
011	Zone 3 target value
100	Zone 4 target value
101	ALS remembers last value after power-save
110	ALS remembers last value after power-save
111	ALS remembers last value after power-save

The ambient light sensor input has a 0 to 1V operational input voltage range. The voltage at ALS1 or ALS2 is compared with the 8-bit values programmed into the Zline0-Zline3 registers. When the ambient light sensor output crosses one of the Zline0 – Zline3 programmed thresholds, the internal ALS circuitry will smoothly transition the LED current to the new 8-bit brightness level as programmed into the Z0 target light – Z4 target light registers. The averaging time for ALS to be configured with 3 bits in ALS control register 11H is described in following table . The averaging time is designed to remove fast changes in lighting conditions.

Table 39. ALS Averaging Time Selection

GENERAL PURPOSE ADC

LM8502 has a built-in analog-to-digital converter (ADC) that can be used, for example, for LED error detection or sensor input for the lighting engines. The general purpose ADC provides an opportunity to measure the forward voltages of the LED outputs as well as flash outputs and Indicator LED Output. Voltage on ALS1 input, boost converter output voltage V_{OUT} and voltage in INT pin can also be measured with the ADC. The ADC is activated by serial interface write and the result can be read through the serial interface during the next cycle. [Table 49](#) describes how to select correct output to be measured.

One can also connect some sensors or audio input for getting sensor or audio synchronization information into lighting engines via ADC. Values from ADC to lighting engines are passed with variables. The ADC can convert positive signals from 0 to 5V.

Table 49. General Purpose ADC Conversion Table

adc_test_ctrl[4:0]	ADC Output
00000	LED Output 1
00001	LED Output 2

Table 49. General Purpose ADC Conversion Table (continued)

10001	INT pin
10010 – 11111	Not used

THERMAL SHUTDOWN

When the LM8502's die temperature reaches +150°C, the boost converter shuts down and the NFET and PFET turn off. Additionally, both flash sources (FLASH1 and FLASH2) turn off. When the thermal shutdown threshold is tripped a '1' is written to bit [1] of the Flag register (Thermal Shutdown bit). The LM8502 will start up again when the die temperature falls to below +135°C.

During heavy load conditions when the internal power dissipation in the device causes thermal shutdown, the part will turn off and start up again after the die temperature cools down. This will result in a pulsed on/off operation.

PWM/ENVM/TX2 PIN

The PWM/ENVM/TX2 pin can be configured as a PWM input, as an external voltage mode enable, or as a power amplifier synchronization. PWM input can be enabled from register 3BH bit [0]. Setting this bit to '0' enables PWM and disables ENVM/TX2.

Table 50. PWM Configuration

INT_pin configuration	PWM_CONFIG (bit [0] register 3BH)
PWM input enabled, ENVM/TX2 disabled	0
PWM input disabled, ENVM/TX2 enabled	1

When the PWM input is enabled the LED current becomes a function of the code in the group brightness register and the duty cycle at PWM. The PWM input accepts a logic level input with selectable minimum frequencies of 100 Hz, 500 Hz, 1 kHz, and 5 kHz. Internal filtering of the PWM input frequency converts the duty cycle information to an average control signal which directly controls the LED current. [Table 51](#) displays latency information for different PWM minimum frequency selections. Minimum frequency can be selected from DBC control register 1DH.

Table 51. PWM Frequency Control

pwm_min_freq control (Hz)	Latency, PWM (100% to 0%), ms	Latency, PWM (0% to 100%), ms
100	13.6	12.2
500	3	2.9
1000	1.7	1.7
5000	0.45	0.7

The PWM input is designed so that it works through the group controls. LED outputs, which should be controlled by the PWM, need to be grouped into one of the three groups. There is an enable for each group that selects whether the PWM affects a certain group or not. One group of LED outputs could be affected by PWM whereas another might only be controlled from a group fader register. After the PWM input is multiplied with the group brightness setting, and possibly also with the ALS0, it is mapped into LED outputs.

ENVM and TX2 are explained in more detail in the Flash section.

INT PIN

The INT pin is used for informing the microcontroller when a lighting sequence is finished, when ALS changes zone, or when the general purpose ADC has finished its measurement. The INT signal is active low, i.e., when an interrupt signal is sent, and the pin is pulled to GND. The INT pin can be configured with bit [1] in register 3BH. Setting this bit to '0' enables the INT; setting it to '1' connects the INT to the general purpose ADC. An external pull-up resistor is needed for proper functionality.

TRIG PIN

The TRIG pin can function as an external trigger input or output. External trigger signal is active low when a trigger is sent or received, and the pin is pulled to GND. TRIG is an open-drain pin, and an external pull-up resistor is needed for trigger line. An external trigger input signal must be at least two 32 kHz clock cycles long to be recognized. The trigger output signal is three 32 kHz clock cycles long. If TRIG pin is not used on application, it should be connected to GND to prevent floating of this pin and extra current consumption.

CLK PIN

The CLK pin is used for connecting an external 32 kHz clock to the LM8502. Using an external clock can improve automatic Power-save mode efficiency because the internal clock can be switched off automatically when device has entered Power-save mode and an external clock is present. The device can be used without an external clock. If an external clock is not used on the application, the CLK pin should be connected to GND to prevent floating of this pin and extra current consumption.

POWER SAVING

The LM8502 includes Power-save mode which allows lower current consumption when the device is not active. Additional power can be saved using an external 32 kHz clock input. Automatic Power-save mode is enabled when the POWERSAVE_EN bit in register is '1'. Almost all analog blocks are powered down in Power-save if an external clock signal is used. Only the protection circuits remain active. However, if the internal clock has been selected, only the boost converter and LED drivers are disabled during the power-save; the digital part of the LED controller needs to stay active. During the program execution the LM8502 can enter Power-save if there is no activity in any of the LED driver outputs. To prevent short power-save sequences during program execution, the device has an instruction look-ahead filter. During program execution engine 1 and engine 2 instructions are constantly analyzed, and if there are time slots with no activity on LED driver outputs for 50 ms, the device will enter Power-save. In Power-save mode program execution continues uninterrupted. When an instruction that requires activity is executed, a fast internal startup sequence will be started automatically.

Figure 23. The Effect of Power-Save Mode During a Lighting Sequence

BOOST CONVERTER

The LM8502 has a 2 MHz fixed-frequency synchronous boost converter. The boost converter has two modes: Constant Voltage Output mode and Adaptive Voltage mode. On startup, when V_{OUT} is less than V_{IN} , the internal synchronous PFET turns on as a current source and delivers 350 mA (typ.) to the output capacitor. During this time all LED outputs are off. When the voltage across the output capacitor reaches 2.2V, the LED outputs can turn on.

Constant Voltage Output Mode

In Constant Voltage Output mode the LM8502 operates as a voltage output boost converter with selectable output voltages of 4.5V and 5V. In Constant Voltage Output mode the LM8502 is able to deliver up to 5W of output power.

Constant Voltage Output mode is enabled by Bit 2 (VM) of the Torch Brightness register or Flash Brightness register, with the ENVM input or with the EN_HAPTIC bit. Write a '1' to bit [1] of Configuration Register 1 to set V_{OUT} to 5V. Write a '0' to this bit to set V_{OUT} to 4.5V. In Constant Voltage Output mode the flash LED current sources continue to operate; however, the difference between V_{OUT} and V_{LED} will be dropped across the current sources. In Constant Voltage Output mode when V_{IN} is greater than V_{OUT} , the LM8502 operates in Pass mode.

Adaptive Voltage Mode

In Adaptive Voltage mode the adaptive boost control is enabled, and the output voltage is kept at optimum level. When the flash outputs are on, and if the output voltage is greater than $V_{IN} - 150$ mV, the PWM converter switches and maintains at least 300 mV across flash LED outputs.

When flash LEDs are not on, the converter maintains at least 70 mV across the low-side LED outputs. Converter voltage is raised in steps from 3.125V up to 5V in 125 mV steps to ensure that the LED outputs remain in regulation. When the input voltage rises above the LED voltage + headroom voltage, the device operates in Pass mode.

When flash and low-side LED outputs are both on, starting level and maximum level for the voltage-over-flash LED driver can be defined. These levels are defined in register 35H according to following table:

Table 52. Adaptive Flash Control Register 35H

FLASH_START[7:4]	FLASH_MAX[3:0]	Voltage-over-flash LED driver (mV)
0000	0000	300
0001	0001	400
0010	0010	500
0011	0011	600
0100	0100	700
0101	0101	800
0110	0110	900
0111	0111	1000
1000	1000	1100
1001	1001	1200
1010	1010	1300
1011	1011	1400
1100	1100	1500
1101	1101	1600
1110	1110	1700
1111	1111	1800

PASS MODE

If the difference between V_{OUT} and V_{LED} is greater than 300 mV the device operates in Pass mode. In Pass mode the boost converter stops switching and the synchronous PFET turns fully on bringing V_{OUT} up to $V_{IN} - I_{IN} \times R_{PMOS}$ ($R_{PMOS} = 150m\Omega$). In Pass mode the inductor current is not limited by the peak current limit. In this situation the output current must be limited to **2.5A**.

If the device is operating in Pass mode, and V_{IN} drops to a point that forces the device into switching, the LM8502 will make a one-time decision to jump into Switching mode. The LM8502 remains in Switching mode until the device is shut down and re-enabled. This is true even if V_{IN} were to rise back above $V_{FLASH LED} + 300$ mV. This prevents the LED current from oscillating when V_{IN} is operating close to V_{OUT} .

LIGHT LOAD

At light loads, whether in Constant Voltage mode or Adaptive Voltage mode, the PWM switching converter changes over to a pulsed frequency regulation scheme (light-load comparator enabled) and only switches as necessary to ensure proper LED current or output voltage regulation. This allows for improved light load efficiency compared to converters that operate in fixed frequency PWM mode at all load currents. In this mode the device will only switch as necessary to maintain V_{OUT} within regulation. This mode provides a better efficiency due to the reduction in switching losses which become a larger portion of the total power loss at light loads.

Configuration Register 1 bit [0] = 1 disables the light-load comparator. With this bit set to '0' (default) the light load comparator is enabled. When flash LEDs are enabled the light load comparator is always disabled. When the light load comparator is disabled the LM8502 will operate at a constant frequency down to $I_{LOAD} = 0$. Disabling light load can be useful when a more predictable switching frequency across the entire load current range is desired.

OVER-VOLTAGE PROTECTION

The output voltage is limited to typically 5.6V (5.7V max). In situations such as when the current source is open, the LM8502 will raise the output voltage in order to try to keep the LED current at its target value. When V_{OUT} reaches 5.6V the over-voltage comparator will trip and turn off both the internal NFET and PFET. When V_{OUT} falls below 5.4V the LM8502 will begin switching again. Note that over-voltage protection is not in use in Pass mode.

CURRENT LIMIT

The LM8502 features 4 selectable current limits 1A, 1.5A, 2A, and 2.5A. These are controlled through the I²C-compatible interface via bits [6:5] of the Flash Duration register. When the current limit is reached the LM8502 stops switching for the remainder of the switching cycle.

Since the current limit is sensed in the NMOS switch there is no mechanism to limit the current when the device operates in Pass mode. In situations where there could potentially be large load currents at OUT, and the LM8502 is operating in Pass mode, the load current must be limited to 2.5A. In Boost mode or Pass mode, if V_{OUT} falls below approximately 2.3V, the part stops switching, and the PFET operates as a current source limiting the current to typically 350 mA. This prevents damage to the LM8502 and excessive current draw from the battery during output short circuit conditions.

MAXIMUM OUTPUT POWER

Output power is limited by three things: the peak current limit, the ambient temperature, and the maximum power dissipation in the package. If the LM8502's die temperature is below the absolute maximum rating of +125°C, the maximum output power can be over 6W. However, any additional output current will cause the internal power dissipation to increase and, therefore increase the die temperature. This can be additionally compounded if the flash LED current sources are operating since the difference between V_{OUT} and V_{LED} is dropped across the current sources. Any circuit configuration must ensure that the die temperature remains below +125°C taking into account the ambient temperature derating.

$$P_{DISS} = \left[\left(\left(\frac{(V_{OUT} - V_{IN}) \times V_{OUT}}{V_{IN}^2} \right) \times R_{NFET} + \left(\frac{V_{OUT}}{V_{IN}} \right) \times R_{PFET} \right) \times I_{LOAD}^2 + P_{DISSLED} \right]$$

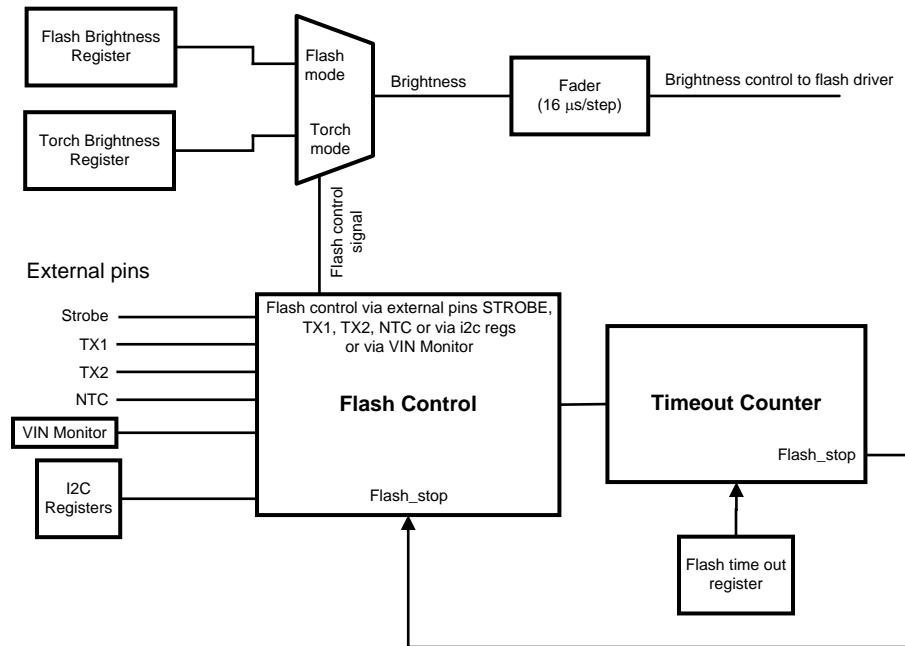

$$P_{DISSLED} = (V_{OUT} - V_{FLASH}) \times I_{FLASH} + (V_{OUT} - V_{IND}) \times I_{IND} + (V_{OUT} - V_{LEDS}) \times I_{LEDS}$$

$$I_{LOAD} = I_{OUT} + I_{FLASH} + I_{IND} + I_{LEDS}$$

$$I_{FLASH} = I_{FLASH1} + I_{FLASH2} \tag{1}$$

The above formulas consider the average current through the NFET and PFET. The actual power losses may be higher due to the RMS currents and the quiescent power. This equation, however, gives a decent approximation.

FLASH

Flash Startup

Turn on of the flash in the LM8502 is done through bits [2:0] of the Torch Brightness register (A0H), bits [2:0] of the Flash Brightness register (B0H), or by pulling the STROBE pin high. Bits [1:0] of the Torch Brightness register or Flash Brightness register set the current sources into Flash = '11', Torch = '10' or Indicator = '01' mode (outputs FLASH1, FLASH2, and LED1). At turn-on the current sources step through each level until the target LED current is reached (16 µs/step). This gives the device a controlled turn-on and limits inrush current from the V_{IN} supply.

Table 53. Flash Modes

EN1 and EN0 bits in Registers A0H or B0H	Flash Mode
00	Flash Shutdown
01	Indicator Mode
10	Torch Mode
11	Flash mode

Table 54. Flash Registers

Register	Bit [7]	Bit [6]	Bit [5]	Bit [4]	Bit [3]	Bit [2]	Bit [1]	Bit [0]
TORCH BRIGHTNESS A0H	INDICATOR LED CURRENT		TORCH CURRENT			VM	EN1	EN0
FLASH BRIGHTNESS B0H	STR	FLASH CURRENT				VM	EN1	EN0
FLASH DURATION C0H	CURRENT LIMIT		FLASH TIMEOUT					
FLAG REGISTER D0H	UVLO FLAG		NTC FLAG	TX2 FLAG	TX1 FLAG	FLASH LED FAULT	TSD FLAG	FLASH TIMEOUT FLAG
CONFIG REGISTER 1 E0H	TX1/TORCH	TX2 POLARITY	TX2_PIN_CONFIG	NTC_HYST	LED1_NTC	DIS_EXT_STROBE	VM_VALUE	DIS_PFM
CONFIG REGISTER 2 F0H	UVLO_LEVEL		EN_UVLO	EN_NTC_INTERRUPT	UVLO_MODE	AET_MODE	NTC_MODE	TX2 SHUTDOWN

Flash Mode

In Flash mode the LED current sources (FLASH1 and FLASH2) each provide 16 different current levels from 37.5 mA to 600 mA in steps of 37.5 mA (see [Table 55](#)). The Flash currents are adjusted by writing to bits [6:3] of the Flash Brightness register, and Flash mode is enabled by writing '11' to Torch Brightness register or Flash Brightness register bits [1:0].

Table 55. Flash Currents

Flash Current Bits [6:3] in Register B0H	Flash Current (mA)/Output
0000	37.5
0001	75
0010	112.5
0011	150
0100	187.5
0101	225
0110	262.5
0111	300
1000	337.5
1001	375
1010	412.5
1011	450
1100	487.5
1101	525
1110	562.5
1111	600

Flash Timeout

The Flash Timeout period sets the amount of time that the Flash Current is being sourced from current sources FLASH1 and FLASH2. Bits [4:0] of the Flash Duration register set the Flash Timeout period. There are 32 different Flash Timeout levels in steps of 32 ms giving a Flash Timeout range of 32 ms to 1024 ms. When timeout expires before Flash pulse is terminated, the FLASH_TIME_OUT bit in Flag Register D0H is set to '1'. This flag is reset to '0' by pulling EN pin low, removing power from the LM8502, or when the next Flash pulse is triggered.

Torch Mode

In Torch mode the current sources FLASH1 and FLASH2 each provide 8 different current levels. (See [Table 56](#)). The Torch currents are adjusted by writing to bits [5:3] of the Torch Brightness register. Torch mode is activated by setting Torch Brightness register or Flash Brightness bits [1:0] to '10'. Once the Torch mode is enabled the current sources will ramp up to the programmed Torch current level by stepping through all of the Torch currents at (16 μ s/step) until the programmed Torch current level is reached.

Table 56. Torch Currents

Torch Current Bits [5:3] in Register A0H	Torch Current (mA)/Output
000	18.75
001	37.5
010	56.25
011	75
100	93.75
101	112.5
110	131.25
111	150

STROBE

Bit [7] of the Flash Brightness register (STR bit) determines how the Flash pulse terminates. With the STR bit = 1 the Flash current pulse will only terminate by reaching the end of the Flash Timeout period. With STR = 0, Flash mode can be terminated by pulling STROBE low, programming bits [1:0] of the Torch Brightness register, or the Flash Brightness register to '00', or by allowing the Flash Timeout period to elapse. If STR = 0, and STROBE is toggled before the end of the Flash Timeout period, the Timeout period resets on the rising edge of STROBE. See LM8502 Timing Diagrams regarding the Flash pulse termination for the different STR bit settings.

After the Flash pulse terminates, either by a flash timeout, pulling STROBE low, or disabling it via the I²C-compatible interface, FLASH1 and FLASH2 turn completely off. This happens even when Torch is enabled via the I²C-compatible interface, and the Flash pulse is turned on by toggling STROBE. After a Flash event ends the EN1 and EN0 bits (bits [1:0] of the Torch Brightness register or Flash Brightness register) are automatically rewritten with '00'.

Power Amplifier Synchronization (TX1)

The TX1/TORCH input has a dual function. When Configuration register 1 bit [7] = 0 (default), EOH TX1/TORCH is a power amplifier synchronization input. This is designed to reduce the current pulled from the battery during an RF power amplifier transmit event. When the LM8502 is engaged in a Flash event, and the TX1/TORCH pin is pulled high, both FLASH1 and FLASH2 are forced into Torch mode at the programmed Torch current setting. If the TX1/TORCH pin is then pulled low before the Flash pulse terminates, the LED current will ramp back to the previous Flash current level. At the end of the Flash timeout, whether the TX1/TORCH pin is high or low, the LED current will turn off.

When Configuration Register 1 bit [7] = 1, TX1/TORCH is configured as a hardware Torch mode enable. In this mode a high at TX1/TORCH turns on the LED current sources in Torch mode. TX1/TORCH will take precedence over the STROBE input and Flash/Torch bit settings of the Torch Brightness register bits [1:0] and the Flash Brightness register bits [1:0].

The TX1 interrupt flag (bit [3]) indicates a TX event on the TX1/TORCH pin. Bit [3] will read back a '1' if TX1/TORCH is in TX1 mode, and the pin has changed from low to high since the last read of the Flag register. A read of the Flag Register automatically resets this bit.

PWM/ENVM/TX2

The PWM/ENVM/TX2 input has three functions. (See above for explanation of PWM function.) ENVM/TX2 can be enabled from bit [0] of register 3BH. Setting this PWM_CONFIG bit to '1' disables PWM and enables ENVM/TX2.

In ENVM mode (Configuration register 1 bit [5] = 0) the ENVM/TX2 pin is an active high-logic input that forces the LM8502 into Voltage Output mode. In TX2 mode (Configuration Register 1 bit [5] = 1) the ENVM/TX2 pin is a power amplifier synchronization input that forces the LM8502 from Flash mode into Torch mode.

In TX2 mode, when Configuration Register 1 bit [6] = 0 the ENVM/TX2 input is an active low-transmit interrupt input. When Configuration Register 1 bit [6] = 1 the ENVM/TX2 input is an active high-transmit interrupt. Under this condition when the LM8502 is engaged in a Flash event, and ENVM/TX2 is pulled low (bit = 0) or high (bit = 1), both FLASH1 and FLASH2 are forced into either Torch mode or LED shutdown, depending on the logic state of Configuration Register 2 bit [0]. After a TX2 event, if the ENVM/TX2 input is disengaged, and the TX2 Shutdown bit is set to force Torch mode, the LED current will ramp back to the previous Flash current level. If the TX2 shutdown bit is programmed to force LED shutdown at a TX2 event, the Flag register must be read to resume normal LED operation.

The TX2 interrupt flag (bit [4]) indicates a TX event on the ENVM/TX2 pin. Bit [4] will read back a '1' if ENVM/TX2 is in TX2 mode, and the pin has had a TX event since the last read of the Flag register. A read of the Flag Register automatically resets this bit.

Indicator LED/Thermistor (LEDI/NTC)

The LEDI/NTC pin serves a dual function, either as an LED indicator driver or as a threshold detector for a negative temperature coefficient (NTC) thermistor.

LED Indicator Mode (LEDI)

LEDI/NTC is configured as an LED indicator driver by setting Configuration register 1 bit [3] = '0' and Torch Brightness register or Flash Brightness register bits [1:0] = '01'. In Indicator mode there are 4 different current levels available (2.3 mA, 4.6 mA, 7.9 mA, 9.2 mA). Bits [7:6] of the Torch Brightness register set the 4 different indicator current levels.

Thermal Comparator Mode (NTC)

Writing a '1' to Configuration register 1 bit [3] disables the indicator current source and configures the LEDI/NTC pin as a detector for a NTC thermistor. In this mode the LEDI/NTC becomes the negative input of an internal comparator with the positive input internally connected to a reference ($V_{TRIP} = 1V$). Additionally, Configuration register 2 bit [1] determines what action the device takes if the voltage at LEDI/NTC falls below V_{TRIP} (while the device is in NTC mode). With Configuration register 2 bit [1] = 0, the LM8502 will be forced into Torch mode when the voltage at LEDI/NTC falls below V_{TRIP} . With Configuration register 2 bit [1] = 1 the device will shut down the current sources when $V_{LEDI/NTC}$ falls below V_{TRIP} . Two software-selectable hysteresis levels are available for NTC mode. Configuration register 1 Bit [4] = 0 selects 125 mV of hysteresis. When this bit is set to 1 there is 250 mV of hysteresis in NTC mode.

The NTC flag bit [5] of the Flag Register reads back a '1' if the LM8502 is active in Flash or Torch mode, the device is in NTC mode, and the voltage at LEDI/NTC has fallen below V_{TRIP} . When this has happened, and the LM8502 has been forced into Torch or LED shutdown (depending on the state of Configuration Register 2 bit [1]), the Flag Register must be read, and the voltage at the LEDI/NTC pin goes above $V_{TRIP} + \text{hysteresis}$ in order to place the device back in normal operation. For example, if the NTC mode has been selected (Configuration Register 1 bit [3] = 1) and programmed to force Torch mode while the device is flashing during an NTC event, the LEDs will then be forced into Torch mode. Until the Flag Register is read back, the LEDs will only be able to flash at the programmed Torch current level. On the other hand, if LED shutdown is selected, the LEDs will remain off regardless of the state of the LED enable bits and STROBE until the Flag Register is read back.

Alternative External Torch Mode

Configuration Register 2 bit [2] programs the LM8502 for Alternative External Torch mode. With this bit set to '0' (default), TX1/TORCH is a transmit interrupt that forces Torch mode only during a Flash event. For example, if TX1/TORCH goes high during a Flash event, the LEDs will be forced into Torch mode only for the duration of the timeout counter. At the end of the timeout counter the LEDs will turn off.

With Configuration Register 2 bit [2] set to '1' the operation of TX1/TORCH depends on STROBE. In this mode if TX1/TORCH goes first, and then STROBE goes high, the LEDs are forced into Torch mode with no timeout. If TX1/TORCH goes high after STROBE has gone high, then the TX1/TORCH pin operates as a normal TX interrupt, and the Flash LEDs will turn off at the end of the timeout duration.

Input Voltage Monitor

The LM8502 has an internal comparator that monitors the voltage at V_{IN} and can force the flash LED current into Torch mode or into shutdown if V_{IN} falls below the programmable Undervoltage Lockout Threshold. Bit 5 in Configuration Register 2 F0H enables or disables the feature. When enabled, Bits [1] and [2] program the 4 adjustable thresholds of 3.1V, 3.2V, 3.3V and 3.4V. Bit [3] in Configuration Register 2 F0H selects whether an undervoltage event forces Torch mode or forces the flash LEDs off.

There is a set 100 mV hysteresis for the input voltage monitor. When the input voltage monitor is active, and V_{IN} falls below the programmed UVLO threshold, the flash LEDs will either turn off or their current will be reduced to the programmed Torch current setting. To reset the flash LED current to its previous level, two things must occur. First, V_{IN} must go at least 100 mV above the UVLO threshold; secondly, the Flag register must be read back.

The UVLO flag (bit [6] of the Flag Register) reads back a '1' when the Input Voltage Monitor is enabled and V_{IN} falls below the programmed UVLO threshold. This flag must be read back in order to resume normal operation after the LED current has been forced to Torch mode or turned off due to a UVLO event.

Flash LED Fault

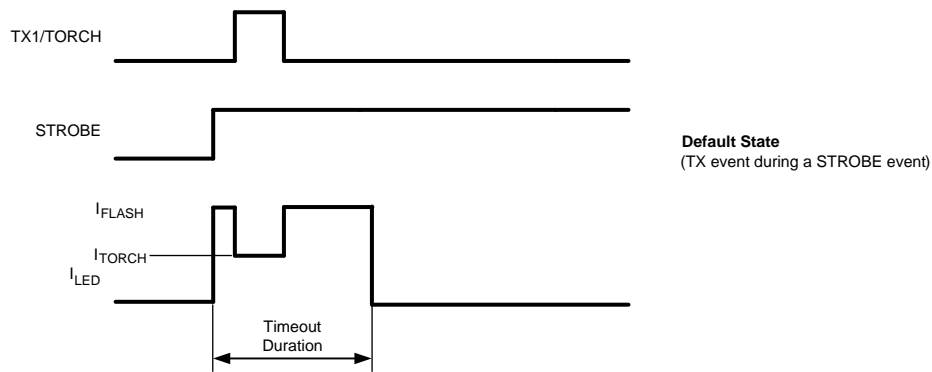

The LED Fault flag (bit [2] of the Flag Register) reads back a '1' if the part is active in Flash or Torch mode, and either FLASH1 or FLASH2 experience an open or short condition. An LED open condition is signaled if the OVP threshold is crossed at OUT while the device is in either Flash or Torch modes. An LED short condition is signaled if the voltage at FLASH1 or FLASH2 goes below 500 mV while the device is in Torch or Flash modes.

There is a small delay before the flash fault flag is valid. This delay is the time between when the Flash or Torch current is triggered and the LED voltage and the output voltage is sampled. The flash fault flag can only be reset to '0' by pulling EN pin low or removing power to the LM8502.

LM8502 Timing Diagrams

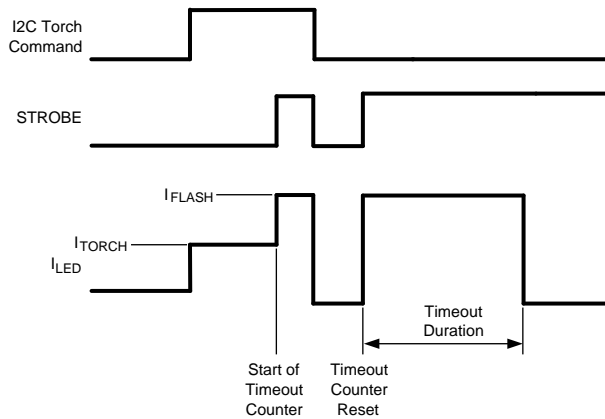

Normal Torch to Flash Operation
 (Default, Power On or RESET state of LM8502)

TX1 Event During a Flash Event
 (Default State, TX1/TORCH is an Active High TX Input)

TX1 Event Before and After Flash Event
 (Default State, TX1/TORCH is an Active High TX Input)

**Default State**

STROBE goes high and the LEDs turn on into Flash mode. LEDs will turn off at the end of timeout duration or when STROBE goes low. Everytime STROBE goes high the timeout resets.

STROBE Input is Level Sensitive
 (Default State, STR bit = 0)
**Flash Brightness Register bit 7 (STR) = 1**

STROBE goes high and the LEDs turn on into Flash mode. LEDs will stay on for the timeout duration even if STROBE goes low before.

STROBE Input is Edge Sensitive
 (STR bit = 1)

ENVM/TX2 as a transmit interrupt
Configuration Register bit 5 (ENVM/TX2) = 1
 (ENVM/TX2 operates as a transmit interrupt)

ENVM/TX2 Pin is Configured as an Active High TX Input

I²C-Compatible Interface

The I²C-compatible synchronous serial interface provides access to the programmable functions and registers on the device. This protocol uses a two-wire interface for bidirectional communications between the IC's connected to the bus. The two interface lines are the Serial Data Line (SDA), and the Serial Clock Line (SCL). Every device on the bus is assigned a unique address and acts as either a Master or a Slave depending on whether it generates or receives the serial clock SCL. The SCL and SDA lines should each have a pull-up resistor placed somewhere on the line and remain HIGH even when the bus is idle. Note: CLK pin is not used for serial bus data transfer. The LM8502 supports high speed I²C.

DATA VALIDITY

The data on SDA line must be stable during the HIGH period of the clock signal (SCL). In other words, state of the data line can only be changed when clock signal is LOW.

Figure 24. Data Validity Diagram

START AND STOP CONDITIONS

The LM8502 is controlled via an I²C-compatible interface. START and STOP conditions classify the beginning and end of the I²C session. A START condition is defined as SDA transitioning from HIGH to LOW while SCL is HIGH. A STOP condition is defined as SDA transitioning from LOW to HIGH while SCL is HIGH. The I²C master always generates the START and STOP conditions.

Figure 25. Start and Stop Sequences

The I²C bus is considered busy after a START condition and free after a STOP condition. During data transmission the I²C master can generate repeated START conditions. A START and a repeated START condition are equivalent function-wise. The data on SDA must be stable during the HIGH period of the clock signal (SCL). In other words, the state of SDA can only be changed when SCL is LOW. shows the SDA and SCL signal timing for the I²C-Compatible Bus. See the Electrical Tables for timing values.

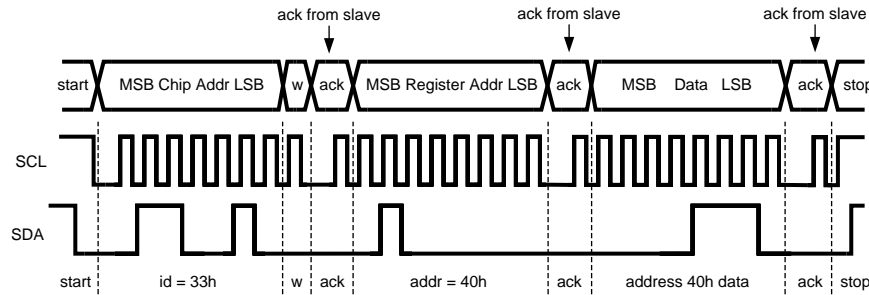

Figure 26. I²C-Compatible Timing

TRANSFERRING DATA

Every byte put on the SDA line must be eight bits long, with the most significant bit (MSB) being transferred first. Each byte of data has to be followed by an acknowledge bit. The acknowledge related clock pulse is generated by the master. The master releases the SDA line (HIGH) during the acknowledge clock pulse. The LM8502 pulls down the SDA line during the 9th clock pulse, signifying an acknowledge. The M8502 generates an acknowledge after each byte has been received.

There is one exception to the “acknowledge after every byte” rule. When the master is the receiver, it must indicate to the transmitter an end of data by not-acknowledging (“negative acknowledge”) the last byte clocked out of the slave. This “negative acknowledge” still includes the acknowledge clock pulse (generated by the master), but the SDA line is not pulled down.

After the START condition, the bus master sends a chip address. This address is seven bits long followed by an eighth bit which is a data direction bit (READ or WRITE). For the eighth bit, a “0” indicates a WRITE and a “1” indicates a READ. The second byte selects the register to which the data will be written. The third byte contains data to write to the selected register.

(w = write; SDA = '0'), id = device address = 33H for LM8502

Figure 27. Write Cycle

(r = read; SDA = '1'), id = device address = 33H for LM8502. When READ function is to be accomplished, a WRITE function must precede the READ function as shown above.

Figure 28. Read Cycle

I²C-COMPATIBLE CHIP ADDRESS

The device address for the LM8502 is '0011 0011' (33H). After the START condition, the I²C master sends the 7-bit address followed by an eighth bit, read or write (R/W). R/W = 0 indicates a WRITE, and R/W = 1 indicates a READ. The second byte following the device address selects the register address to which the data will be written. The third byte contains the data for the selected register.

Figure 29. Device Address

AUTO INCREMENT FEATURE

The auto increment feature allows writing several consecutive registers within one transmission. Every time an 8-bit word is sent to the LM8502, the internal address index counter will be incremented by one, and the next register will be written. The table below shows writing a sequence to two consecutive registers. Note that auto increment feature does not work for read.

Table 57. Auto Increment Example

Master	Start	Device Address = 33H	Write		Register Address		Data		Data		Stop
LM8502				ACK		ACK		ACK		ACK	

Register Descriptions

The LM8502 is controlled with set of registers through the I²C-compatible interface. [Table 58](#) below lists device registers, their addresses and abbreviations.

Table 58. Detailed Register Descriptions

Hex Address	Register Name	Bit(s) in Use	Read/Write	Bit Default Value After Reset	Bit Mnemonic and Description
00	ENABLE/ENGINE CNTRL1	[6]	R/W	0	CHIP_EN 0 = LM8502 not enabled. Device enters Standby mode. Control registers can be written or read. 1 = LM8502 enabled and internal startup sequence powers up all needed internal blocks and device enters Normal mode.
		[5:4]	R/W	00	ENGINE1_EXEC Engine 1 program execution control. Execution register bits define how the program is executed. Program start address can be programmed to Program Counter (PC) register 37H. 00 = Hold: Hold causes the execution engine to finish current instruction and the stop. PC can be read or written only in this mode. 01 = Step: Execute the instruction at the location pointed by PC, increment PC by one and then reset ENG1_EXEC bits to 00. 10 = Free Run: Start program execution from the instruction pointed by PC. 11 = Execute Once: Execute the instruction pointed by the current PC value and reset ENG1_EXEC to 00. The difference between step and execute once is that execute once does not increment PC.
		[3:2]	R/W	00	ENGINE2_EXEC Engine 2 program execution control. Equivalent to engine 1 control bit. Program start address can be programmed to PC register 38H.
01	ENGINE CNTRL2	[5:4]	R/W	00	ENGINE1_MODE Engine 1 mode control: 00 = Disabled: Engines can be configured to disabled mode separately. 01 = Load program to SRAM memory, reset PC. Writing to program memory is allowed only when the engine is in load program mode and engine busy bit (3AH) is not set. Serial bus master should check the busy bit before writing to program memory. Both engines are in hold while one is in Load mode. Load mode resets the PC of the respective engine. Load mode can be entered only from Disabled mode. Entering Load mode from Run mode is not allowed. 10 = Run mode executes the instructions stored in the program memory. Engine control register bits define how the program is executed. Program start address can be programmed to PC register. PC is reset to zero when the PC upper limit is reached. 11 = Halt mode halts the engine operation and instruction execution is aborted immediately.
		[3:2]	R/W	00	ENGINE2_MODE Engine 2 mode control, same as Engine 1.

Table 58. Detailed Register Descriptions (continued)

02 – 04	GROUPS 1 – 3 FADING	[7:4]	R/W	0000	FADE_IN Fade in time for groups 1 – 3 See fade_in times in ⁽¹⁾
		[3:0]	R/W	0000	FADE_OUT Fade out time for groups 1 – 3 See fade_out times in ⁽¹⁾
06 – 0F	LED 1 – 10 CONTROL	[7:6]	R/W	00	GROUP_SELECT Group fader selection for LED outputs 1 – 10: 00 = LED output not grouped to any of the groups. Default setting. 01 = Fader group 1 controls the LED output. User can set the overall output of the group from the GROUP 1 FADER register 48H and the fade-in/out times from the GROUP 1 FADING register 02H. 10 = Fader group 2 controls the LED output. User can set the overall output of the group from the GROUP 2 FADER register 49H and the fade-in/out times from the GROUP 2 FADING register 03H. 11 = Fader group 3 controls the LED output. User can set the overall output of the group from the GROUP 3 FADER register 4AH and the fade-in/out times from the GROUP 3 FADING register 04H.
		[5]	R/W	0	LOG_EN Logarithmic dimming control for LED output 1 – 10. This bit is effective for both the program execution engine control and direct PWM control. 0 = linear adjustment 1 = logarithmic adjustment
		[4:3]	R/W	00	FULL_SCALE_SEL Current full-scale setting for LED outputs 1 – 10: 00 = maximum LED current is 3 mA 01 = maximum LED current is 6 mA 10 = maximum LED current is 12.5 mA 11 = maximum LED current is 25.5 mA
		[0]	R/W	0	LED_BAT_CON LED outputs 1 – 10 power selection: 0 = LED powered from VOUT 1 = LED powered from external voltage supply
10	HAPTIC_CONTROL	[7:6]	R/W	00	GROUP_SELECT Group fader selection for Haptic feedback outputs: 00 = Haptic output not grouped to any of the groups. Default setting. 01 = Fader group 1 controls the haptic output. User can set the overall output of the group from the GROUP 1 FADER register 48H and the fade-in/out times from the GROUP 1 FADING register 02H. 10 = Fader group 2 controls the haptic output. User can set the overall output of the group from the GROUP 2 FADER register 49H and the fade-in/out times from the GROUP 2 FADING register 03H. 11 = Fader group 3 controls the haptic output. User can set the overall output of the group from the GROUP 3 FADER register 4AH and the fade-in/out times from the GROUP 3 FADING register 04H.

APPLICATION INFORMATION

APPLICATION DESCRIPTION

The LM8502 can be used in multiple applications. With two Flash/ Haptic outputs and 10 low-side outputs, the LM8502 is usable in flash applications as well as in general illumination applications.

The current sink drivers provide full-scale current setting and current range up to 25.5 mA with maximum full-scale current setting. Each LED output can be powered either from V_{OUT} or from external voltage supply. LED outputs can be used for backlight applications as well as for fun lighting. For backlight applications the LM8502's LED outputs may be grouped and controlled from one register; fading on and off times may be set for the group. LED outputs can be freely grouped into one of the three groups. Two ambient light sensor inputs support the backlight application (LED output 10 is optional) with the secondary ambient light sensing input. The incorporated input for PWM signal enables dynamic backlight control.

For fun lighting the LM8502 offers lighting engines. Controlling outputs with engines enables flexible programming including ramps, loops, and triggering, among others. Programmable lighting engines enable impressive lighting sequences. Once the program is loaded into the LM8502's memory and the program started, the device handles running of the lighting sequence, and no I²C writes are needed during execution. Engines can be set to start with external triggering, and they can send interrupt to the MCU via INT pin.

For Flash applications the LM8502 offers an external Strobe pin, power amplifier synchronization or hardware torch enable (TX1), as well as another power amplifier synchronization input or Voltage mode enable (TX2). The flash driver is capable of delivering 1.2A to a single flash LED or 600 mA into two parallel LEDs. The device also features an indicator LED to, for example, indicating flash events. A threshold detector for a negative temperature coefficient thermistor can detect temperature near flash LEDs. Indicator and NTC are on the same pin and alternate with each other.

When Flash driving capability is not needed, the outputs can be used, for example, to drive a vibra motor. The LM8502 includes controls for enabling different kind of modes and PWM frequencies when driving a vibra motor. The device also has an 8-bit register for haptic PWM control; the outputs can also be grouped or be driven from lighting engines. When one wants to use both a vibra motor and flash on same application, two external FETs are needed to disable the flash while running the vibra motor. This kind of application is shown in the figures below. LED output 10 is set to control the FET status. When driving the flash haptic should be disabled.

Other features of the LM8502 include an external clock input pin, which enables efficient Power-save mode. In Power-save mode almost all the analog blocks are shut down. Also, a general-purpose analog-to-digital converter (ADC), which can be used, for example, to measure the LED voltages, is featured in the LM8502. This general purpose ADC, combined with lighting engines, enables use of different sensors or audio synchronization. Sensor or audio synchronization input can be connected to, for example, the INT pin. The value of the INT pin is read with the general-purpose ADC. This value can be passed to the lighting engines with variables and be used to control the lighting effects.

APPLICATION COMPONENTS

Output Capacitor Selection

The LM8502 is designed to operate with a ceramic output capacitor of at least 4.7 µF in LED mode and a 10 µF output capacitor in Voltage Output mode. When the boost converter is running, the output capacitor supplies the load current during the boost converters on-time. When the NMOS switch turns off, the inductor energy is discharged through the internal PMOS switch, thus supplying power to the load and restoring charge to the output capacitor. This causes a sag in the output voltage during the on-time and a rise in the output voltage during the off-time. The output capacitor is, therefore, chosen to limit the output ripple to an acceptable level depending on load current and input/output voltage differentials and also to ensure the converter remains stable.

For proper LED operation the output capacitor must be at least 10 µF and ceramic. Larger capacitors such as a 22 µF can be used if lower output voltage ripple is desired. To estimate the output voltage ripple considering the ripple due to capacitor discharge (ΔV_Q) and the ripple due to the capacitors ESR (ΔV_{ESR}) use the following equations:

For Continuous Conduction mode, the output voltage ripple due to the capacitor discharge is:

$$\Delta V_Q = \frac{I_{LED} \times (V_{OUT} - V_{IN})}{f_{SW} \times V_{OUT} \times C_{OUT}} \quad (2)$$

The output voltage ripple due to the output capacitors ESR is found by:

$$\Delta V_{ESR} = R_{ESR} \times \left(\frac{I_{LED} \times V_{OUT}}{V_{IN}} \right) + \Delta I_L$$

where

$$\Delta I_L = \frac{V_{IN} \times (V_{OUT} - V_{IN})}{2 \times f_{SW} \times L \times V_{OUT}} \quad (3)$$

In ceramic capacitors the ESR is very low so assume that **80%** of the output voltage ripple is due to capacitor discharge and **20%** from ESR. [Table 59](#) lists different manufacturers for various output capacitors and their case sizes suitable for use with the LM8502.

Input Capacitor Selection

Choosing the correct size and type of input capacitor helps minimize the voltage ripple caused by the switching of the LM8502's boost converter and reduces noise on the device's input terminal that can feed through and disrupt internal analog signals. In the [Typical Application Circuits](#), a 10 μF ceramic input capacitor works well. It is important to place the input capacitor as close as possible to the LM8502's input terminals. This reduces the series resistance and inductance that can inject noise into the device due to the input switching currents. [Table 59](#) lists various input capacitors that are recommended for use with the LM8502.

Table 59. Recommended Input/Output Capacitors (X5R Dielectric)

Manufacturer	Part Number	Value	Case Size	Voltage Rating
TDK Corporation	C1608JB0J106M	10 μF	0603(1.6mm×0.8mm×0.8mm)	6.3V
TDK Corporation	C2012JB1A106M	10 μF	0805(2mm×1.25mm×1.25mm)	10V
TDK Corporation	C2012JB0J226M	22 μF	0805(2mm×1.25mm×1.25mm)	6.3V
Murata	GRM21BR61A106KE19	10 μF	0805(2mm×1.25mm×1.25mm)	10V
Murata	GRM21BR60J226ME39L	22 μF	0805(2mm×1.25mm×1.25mm)	6.3V

Inductor Selection

The LM8502 is designed to use a 2.2 μH inductor. [Table 60](#) lists various inductors and their manufacturers that can work well with the LM8502. When the device is boosting ($V_{\text{OUT}} > V_{\text{IN}}$) the inductor will typically be the biggest area of efficiency loss in the circuit. Therefore, choosing an inductor with the lowest possible series resistance is important. Additionally, the saturation rating of the inductor should be greater than the maximum operating peak current of the LM8502. This prevents excess efficiency loss that can occur with inductors that operate in saturation and prevents overheating of the inductor and possible damage. For proper inductor operation and circuit performance ensure that the inductor saturation and the peak current limit setting of the LM8502 is greater than I_{PEAK} . I_{PEAK} can be calculated by:

$$I_{\text{PEAK}} = \frac{I_{\text{LOAD}}}{\eta} \times \frac{V_{\text{OUT}}}{V_{\text{IN}}} + \Delta I_L \quad \text{where} \quad \Delta I_L = \frac{V_{\text{IN}} \times (V_{\text{OUT}} - V_{\text{IN}})}{2 \times f_{\text{SW}} \times L \times V_{\text{OUT}}} \quad (4)$$

$f_{\text{SW}} = 2\text{MHz}$, and efficiency can be found in the Typical Performance Characteristics plots.

Table 60. Recommended Inductors

Manufacturer	L	Part Number	Dimensions (L×W×H)	I_{SAT}
Coilcraft	2.2 μH	LPS3015–222	3mm×3mm×1.2mm	2.3A
TDK	2.2 μH	VLS252012T-2R2M1R3	2mm×2.5mm×1.2mm	1.5A

NTC Thermistor Selection

NTC thermistors have a temperature to resistance relationship of:

$$R(T) = R_{25^\circ\text{C}} \times e^{\left[\beta \left(\frac{1}{T^\circ\text{C} + 273} - \frac{1}{298} \right) \right]} \quad (5)$$

where β is given in the thermistor datasheet and $R_{25^\circ\text{C}}$ is the thermistors value at $+25^\circ\text{C}$. R_3 in [Figure 38](#) is chosen so that it is equal to:

$$R_3 = \frac{R_{T(\text{TRIP})} (V_{\text{BIAS}} - V_{\text{TRIP}})}{V_{\text{TRIP}}} \quad (6)$$

where $R(T)_{\text{TRIP}}$ is the thermistor's value at the temperature trip point, V_{BIAS} is shown in [Figure 37](#), and $V_{\text{TRIP}} = 1\text{V}$ (typ.). Choosing R_3 here gives a more linear response around the temperature trip voltage. For example, with $V_{\text{BIAS}} = 2.5\text{V}$, a thermistor whose nominal value at $+25^\circ\text{C}$ is 100 k Ω , and a $\beta = 4500\text{K}$, the trip point is chosen to be $+93^\circ\text{C}$. The value of $R(T)$ at 93°C is:

$$R(T) = 100 \text{ k}\Omega \times e^{\left[\frac{\beta}{\left(\frac{1}{93 + 273} - \frac{1}{298} \right)} \right]} = 6.047 \text{ k}\Omega$$

$$R3 \text{ is then: } \frac{6.047 \text{ k}\Omega \times (2.5 \text{ V} - 1 \text{ V})}{1 \text{ V}} = 9.071 \text{ k}\Omega \quad (7)$$

Figure 37 shows the linearity of the thermistor resistive divider of the previous example. With the internal hysteresis set to 125 mV the comparator output will trip and turn the Flash current back on if the thermistor temperature drops to approximately +86°C.

Figure 37. Thermistor Resistive Divider Response vs Temperature

Another useful equation for the thermistor resistive divider is developed by combining the equations for R3, and R(T) and solving for temperature. This gives the following relationship.

$$T(^{\circ}\text{C}) = \frac{\beta \times 298^{\circ}\text{C}}{298^{\circ}\text{C} \times \text{LN} \left(\frac{V_{\text{TRIP}} \times R3}{(V_{\text{BIAS}} - V_{\text{TRIP}}) \times R_{25^{\circ}\text{C}}} \right) + \beta} - 273^{\circ}\text{C} \quad (8)$$

Using a spreadsheet such as Excel, different curves for the temperature trip point T(°C) can be created vs R3, Beta, or VBIAS in order to better help choose the thermal components for practical values of thermistors, series resistors (R3) or reference voltages for VBIAS.

Programming bit [3] of Configuration Register 1 with a '1' selects Thermal Comparator mode making the LED/NTC pin a comparator input for flash LED thermal sensing. Figure 38 shows the internal block diagram of the thermal-sensing circuit which is OR'd with both the TX1 and ENVN/TX2 (TX2 mode) to force the LM8502 from Flash to Torch mode. This is intended to prevent LED overheating during flash pulses. In NTC mode the internal comparator has a selectable 125 mV or 250 mV hysteresis (see Configuration Register 1, Bit [4]).

The termination of the thermistor must be done directly to the cathode of the Flash LED. This will provide the best thermal coupling (lowest thermal resistance). Consequently, with the thermistor tied to the LED's cathode, the thermistor's return can potentially see large GND currents.

Figure 38. Thermistor Voltage Divider and Sensing Circuit

Layout Recommendations

The high frequency and large switching currents of the LM8502 make the choice of layout important. The following steps should be used as a reference to ensure the device is stable and maintains proper voltage and current regulation across its intended operating voltage and current range.

1. Place C_{IN} as close as possible to the V_{IN} terminal and the GND terminal.
2. Place C_{OUT} as close as possible to the OUT terminal and the GND terminal. The returns for both C_{IN} and C_{OUT} should come together at one point, and as close to the GND pin as possible. This will reduce the series inductance and limit noise at the GND pin that will inject noise into the device.

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

Important Information and Disclaimer:The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

TAPE AND REEL INFORMATION

QUADRANT ASSIGNMENTS FOR PIN 1 ORIENTATION IN TAPE

*All dimensions are nominal

Device	Package Type	Package Drawing	Pins	SPQ	Reel Diameter (mm)	Reel Width W1 (mm)	A0 (mm)	B0 (mm)	K0 (mm)	P1 (mm)	W (mm)	Pin1 Quadrant
LM8502TME/NOPB	DSBGA	YFQ	30	250	178.0	8.4	2.67	2.95	0.76	4.0	8.0	Q1
LM8502TMX/NOPB	DSBGA	YFQ	30	3000	178.0	8.4	2.67	2.95	0.76	4.0	8.0	Q1

TAPE AND REEL BOX DIMENSIONS

*All dimensions are nominal

Device	Package Type	Package Drawing	Pins	SPQ	Length (mm)	Width (mm)	Height (mm)
LM8502TME/NOPB	DSBGA	YFQ	30	250	208.0	191.0	35.0
LM8502TMX/NOPB	DSBGA	YFQ	30	3000	208.0	191.0	35.0

YFQ0030

D: Max = 2.803 mm, Min = 2.742 mm

E: Max = 2.436 mm, Min = 2.376 mm

NOTES: A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M-1994.
B. This drawing is subject to change without notice.

IMPORTANT NOTICE AND DISCLAIMER

TI PROVIDES TECHNICAL AND RELIABILITY DATA (INCLUDING DATA SHEETS), DESIGN RESOURCES (INCLUDING REFERENCE DESIGNS), APPLICATION OR OTHER DESIGN ADVICE, WEB TOOLS, SAFETY INFORMATION, AND OTHER RESOURCES "AS IS" AND WITH ALL FAULTS, AND DISCLAIMS ALL WARRANTIES, EXPRESS AND IMPLIED, INCLUDING WITHOUT LIMITATION ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT OF THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

These resources are intended for skilled developers designing with TI products. You are solely responsible for (1) selecting the appropriate TI products for your application, (2) designing, validating and testing your application, and (3) ensuring your application meets applicable standards, and any other safety, security, regulatory or other requirements.

These resources are subject to change without notice. TI grants you permission to use these resources only for development of an application that uses the TI products described in the resource. Other reproduction and display of these resources is prohibited. No license is granted to any other TI intellectual property right or to any third party intellectual property right. TI disclaims responsibility for, and you will fully indemnify TI and its representatives against, any claims, damages, costs, losses, and liabilities arising out of your use of these resources.

TI's products are provided subject to [TI's Terms of Sale](#) or other applicable terms available either on [ti.com](#) or provided in conjunction with such TI products. TI's provision of these resources does not expand or otherwise alter TI's applicable warranties or warranty disclaimers for TI products.

TI objects to and rejects any additional or different terms you may have proposed.
